**15. X-Rays in Carcinomatous Growths.**—This third article by Hopkins gives the general facts of the effect of these rays on diseased cell growth. The author has come to the conclusion that the larger proportion of these growths can be absolutely controlled, and he favors the soft tube for this kind of work, and the static machine as a source of electric energy. His turn, he says, may come for burns, but it will not be for want of precaution; he thinks they can be avoided if necessary care is taken. Lately he has been treating inoperable cases of uterine cancer with considerable success and has had gratifying results in hemorrhagic cancer of the uterine neck and vaginal walls, employing the Finsen light as well as the *x*-ray. He prefers in these cases the hard tube as it has to its credit more injuries to the deep tissues, and therefore penetrates more deeply. The use of an aluminum screen he considers dangerous, as it leads to recklessness from a sense of false security. One of the most satisfactory fields for this work is recurrent cancer after amputation of the breast, and this has given him the most satisfactory results. When ulceration has not occurred in these breast cases, nearly every case will yield to treatment without the destruction of the superimposed skin. Where the skin has been destroyed over the region of disease the ulceration will heal promptly. Gastric carcinomas require the greatest amount of care and judgment and it is better to err on the side of the short exposure. The offensive odor, especially in face carcinomas, is quickly relieved and the *x*-ray has worked marvels in cancer involving the tongue where speech has been lost and swallowing has become so difficult that rectal enemata were required to support the patient. He has had one case where amputation of the tongue was decided on as the growth was closing both the trachea and the esophagus, that yielded to the combined use of the Finsen light and the *x*-ray. After five treatments in three weeks the patient was able to eat solid food and had regained speech.

**18. Fracture of the Humerus.**—Beck reports a case with skiagraphic illustrations. The diagnosis without these would have been erroneous, and he recommends it as a practice for a surgeon to draw a sketch of his diagnosis and see how the skiagram supports it. In the case reported he had to move the arm to fit the smaller fragment and fixed it in extension from the shoulder for two weeks. In seven weeks the function of the arm was perfectly restored.

**19. Appendicitis and Gall-Bladder Disease.**—Kennedy reports several cases diagnosed as appendicitis, one of which turned out to be gall-bladder disease and another biliary colic followed by symptoms suggesting biliary trouble, proving to be appendicitis complicated by a large concretion resembling a gallstone. He thinks that when very similar symptoms are

present in both diseases, the ailments of the appendix too often get the benefit of the doubt.

**20. Pulmonary Embolism.**—Ten cases have been collected by Keyes which seemed to belong to this class, two of which were verified by autopsy, and two more by *prima facie* symptoms of embolism, and may be classed as probable. Four were possible examples and two that he mentions are improbable. He calls attention particularly to the possibility of this accident from operation for prostatic disease and suggests that it is a real element in the prognosis, and that the sooner it is realized the better. Any tearing, cutting or burning of this organ must assuredly cause a certain amount of vesical thrombosis with its associated inflammatory reaction, and when the sluggish portal circulation is considered, the wonder is not that thrombosis should be frequent, but that it should be rare. Add the shock of the operation upon the vitality of an old man, the inevitable uremia for the first few days, and the wonder grows that embolism should not more frequently result. Perhaps it does result more often than we think. He asks the following questions: Is it frequent or not? Are we confronted with a danger we can not meet or will means be discovered to prevent it? Is thrombosis encouraged by the rough torsion of the *rongeur*? Is it due to infiltration following Bottini's operation? Does it ever extend from the gland itself or is it due to injury of the periprostatic plexus? Are phleboliths concerned in its production? Are there any signs by which it may be recognized and means by which it may be prevented? These questions naturally present themselves, but he can not answer them.

21.—See abstract in *THE JOURNAL* of February 8, p. 413.

**24. Puerperal Septicemia.**—The points upon which Vineberg lays special stress are: 1. Every case of puerperal sepsis is a wound fever or a wound infection and should be treated as such. 2. Each case of puerperal sepsis, however slight, should be carefully watched from the onset. We can not tell into what it may develop. 3. When a case of uterine sepsis progresses unfavorably after curetting, irrigation and proper general treatment, as evidenced by the pulse, temperature and the conditions of the uterus, we are justified in opening the abdomen and removing the uterus unless we find some conditions outside of the uterus to account for the persistence of the sepsis, or some condition in the uterus itself, as a single intramural abscess or a localized gangrene, which would admit of removal without ablation of the whole organ. 4. When a uterine infection extends to a tube or ovary, setting up a violent grade of salpingitis or ovarian abscess, the abdomen should be opened without delay and the affected tube or ovary removed. 5. When a uterine infection sets up a septic peritonitis the abdomen should be opened and the uterus ablated, the peritoneal cavity flushed with saline solution and free drainage employed through the vaginal opening. 6. To operate for these conditions, when the patient is evidently moribund, is unjustifiable and can only discredit the profession.

**25. Leucocytosis in Appendicitis.**—The value of the leucocyte count as a point of prognosis in appendicitis is insisted upon by Joy and Wright. They do not depend on it for diagnosis, but as a symptom of the severity of the disease. They summarize their views as follows: 1. The leucocyte count is a valuable aid to prognosis in appendicitis. 2. This is distinct from its diagnostic value. 3. A high stationary, or an increasing, count indicates a morbid condition of increasing severity which demands operation, no matter what the clinical symptoms may be. 4. A low stationary or decreasing count indicates that the severity of the case is abating and that operation may be safely postponed. Cases in which a falling count is accompanied by unmistakable signs of a generally bad condition form the rare exception to this second principle, and in them there is no chance of error. 5. No arbitrary set of prognostic values to be assigned to various degrees of leucocytosis can be constructed. The important point is to follow any scheme in which one learns to have confidence, provided the essential principle be preserved. 6. The count indicates when operation should be performed for the best interests of the

patient. 7. Circumstances often render it desirable to postpone operation in appendicitis. Study of the blood-count enables it to be determined whether this may be done with safety and often renders such postponement permissible.

**28. Malaria.**—Ford reports cases simulating appendicitis, broncho-pulmonary disorder and typhoid fever, and calls particular attention to the unclassified fevers of the tropics leading to mistakes in diagnosis. He considers that in these occur the greatest amount of errors and that they offer the greatest opportunity for investigation.

**29. Suprarenal Extract in Pneumonia.**—Gray recommends and reports cases of the use of suprarenal extract in pneumonia which seem to have, according to his accounts, excellent results. He thinks we have in it the most favorable heart stimulant, which we are at liberty to use in the presence of heart failure impeding the pulmonary circulation as in pneumonia with co-existing renal inflammation. He has noticed a peripheral increase of the blood pressure in a few cases, but this was not permanent.

**30. Artificial Sphincter Ani.**—Chetwood reports a case where a sphincter was apparently destroyed by injury, and, though eight or nine operations had been performed to endeavor to restore the continuity, it was still unsuccessful. He made a large semi-circular incision with its convexity in the direction of the coccyx, from a point about one inch in front of the anterior limit of the anus, on a line, externally, with the tuberosity of the ischium on one side to a similar point on the opposite side, and then turned down a flap. He next dissected out a ribbon-shaped piece of muscular tissue about one and one-fourth inches in breadth on each side from the glutei muscles, leaving an attachment above. Then transposing them, he crossed the lower ends each to the opposite side, underneath the ligamentous connection between the anus and coccyx, encircling the rectum and fastened them with sutures of chromicized catgut. The finger in the rectum now recognized the constriction formed by this arrangement. The flap dissected away was sutured back again in place and the operation was a perfect success.

**31. Antisepsis in Midwifery.**—Browne protests against the use of douches, believing that bichlorid may produce toxic effects and that the natural secretions are antiseptic. In his experience of 26 years he has had 6 cases of puerperal fever, 3 of them treated by strict conformity with the antiseptic method, of which 2 died, and 1 recovered, and 3 treated without antisepsis, with 1 death and 2 recoveries. His results in obstetrics are generally much better without the douche than with it. He also speaks in favor of the use of ergot for expediting labor when the pains have become feeble and the os is completely dilated.

**32. Appendicitis.**—The diagnosis of appendicitis is discussed by Elsberg, who believes we can best diagnose the locality of the disease by the following method: Ask the patient to point the finger quickly at the spot where there is the most pain without looking at the abdomen. Repeat this proceeding a number of times until you are certain that the right point has been obtained. Then the course of the appendix will lie between the base of the organ and this point. Where no mass can be felt in the region it is impossible correctly to diagnose a perforation or gangrene. Where the mass can be felt and persists longer than two or three days without diminishing in size or indeed even increasing, it always has pus for a nucleus. When the mass is to be felt by rectal examination it means an inflamed appendix partially in the pelvis, or a secondary abscess, adhesion in Douglas' pouch, or a gravitation of fluid into the pelvis. One can not lay down fixed rules for the conditions of the general peritoneal cavity, but the author is inclined to believe in rigidity as one of the most striking features. The differential diagnosis between appendicitis and other diseases is generally easy. Occasionally gall-bladder disorder, torsion of the omentum, new growths in the intestine, intestinal obstruction, an affection of the female adnexa, or reflected pain from thoracic disease may make it difficult. The frequency of appendicitis must be kept in mind and that it occurs most fre-

quently in late spring and summer months. The severest cases occur in the large cities. No fixed rules can be laid down for appendicitis. Sometimes the severity of the disease is not in sufficient proportion to account for the symptoms. Sometimes the local symptoms are slight and the general intoxication severe. We have to depend on the pulse, pain, temperature and other symptoms as indications of the severity of the disease and of the treatment to be followed.

43.—See abstract in *THE JOURNAL* of February 22, p. 529.

**47. Infantile Hepatic Cirrhosis.**—This is a rare condition, according to Walls, affecting male children more than female, and with alcoholism in about 20 per cent. of the reported cases and syphilis in about 10 per cent. as an etiologic factor. Tuberculosis is a relatively frequent causative factor. Chronic sepsis has been noted as a cause and acute infectious diseases have been considered as potent causative exciters, though not unequivocally connected with acute instances. He describes the symptoms, the gastro-intestinal disorders that usher it in, icterus, ascites, venous stigmata on the face, hard, large and readily palpable liver, etc. The diagnosis is not always easy, as some of the symptoms in the adult may be lacking and some other infantile diseases like chronic peritonitis have a somewhat similar symptomatology. A large liver and spleen, icterus, suggillations of the skin, hemorrhages from the mouth and intestinal tract, and the presence of free fluid in the peritoneal cavity would indicate this disorder. The prognosis is unfavorable and the course rapid. If we could anticipate the disease before it comes on much might be done, but therapy thus far has been ineffective.

**50. Latent Malaria.**—Young understands by this term a condition in which, following an infection differing in no ascertainable respect from one producing malarial symptoms in the usual time, clinical manifestations are absent, or are delayed for weeks, although the parasites may be more or less constantly present in the circulation and follow (as far as can be determined) their normal intracorporeal life-history. He groups these roughly into two classes: 1. Cases of long incubation followed by an outbreak without an apparently immediate exciting cause. 2. Those where there are, so far as can be seen, no clinical manifestations, or if they do occur their onset seems to be determined by some existing cause entirely independent of the malarial infection. The hypotheses that the parasites lie dormant in the spleen or bone marrow, or that they multiply so slowly that they fail to produce a febrile reaction, are not fully accepted by him and he thinks that, under certain circumstances, the apparent dormancy of the parasites may be due to their following, under the influence of conditions not at all understood, an entirely different life cycle. He gives his reasons for this belief and calls attention to the clinical importance of the condition, suggesting that in any section where malaria is endemic we should not be satisfied in obscure cases of illness of any character, from hysteria to dyspepsia, until we thoroughly examine the blood.

**54. Hemoptysis.**—The importance of pulmonary hemorrhage is insisted upon by Eliot, who quotes Stricker's investigations to show its significance as a premonitory indication of tuberculosis. He notes that most persons have temporary improvement following the arrest of hemorrhage and gives details of the treatment.

**55. Syphilis Domestica.**—Boutelle's paper reports several cases of syphilis occurring in persons in whom it would not be suspected. He thinks we should not be blinded to the existence of this condition by respectability, refinement, innocence or purity of life, as they are not always safeguards.

**63. Localization of Mental Faculties.**—The cases reported by Phelps are those of injury or tumors of the left frontal lobes in which decided mental symptoms existed, while in others of the right frontal lobe, the mental functions were far less affected and often unimpaired. He reviews the literature and finds in every case but two (in which consciousness was retained and the mental faculties were not perverted by general delirium) that the laceration involving the left frontal lobe was attended by default of intellectual control, and that the

lesion is usually, if not always, of the prefrontal region implicating either its superior or inferior surface. Subcortical disintegration, or deep or extensive laceration of the cortex, was specially characterized by abrogation of mental power, and superficial laceration by aberration in its manifestations. Of the two exceptional cases, in one the final coma occurred within two hours after injury and it might, therefore, be excluded; the other one was exceptional only in being regarded as normal for one day in which the patient emerged from a general condition of stupor. The abrogation of mental power seems to be proportionate to the extent of the lesion rather than to its situation in the prefrontal region. In every case where laceration was confined to the right frontal lobe the mental faculties were unaffected, except as they were obscured by stupor or delirium occasioned by coincident general lesion. Compression or contusion of the left lobe only exceptionally produced specific intellectual disturbance. There are also many cases unverified by necropsy and, therefore, debarred in evidence which he thinks are scarcely less convincing.

**67. Albuminous Expectoration.**—Tapping of the chest for the removal of fluids is ordinarily so safe that the idea of serious accident, as Riesman remarks, rarely enters the physician's mind. That such accidents may occur, however, is important and Riesman reports a case and finds others in the literature. The expectoration was carefully analyzed and the theories of the phenomenon of albuminous expectoration are discussed. The following are the author's conclusions: "1. Albuminous expectoration is a very rare complication of thoracentesis. It is usually serious and sometimes fatal. 2. It consists in the expectoration of a viscid albuminous fluid closely resembling the fluid of serous effusion. 3. The condition is best explained on the basis of an intense congestion and edema of the lungs (congestion by recoil). 4. The principal cause seems to be either too rapid or too great a withdrawal of fluid. 5. Serious cardiac disease and morbid conditions of the opposite lung, hindering expansion, are predisposing causes. 6. Under all circumstances, but particularly when these complications exist, aspiration should be performed slowly. If the effusion is large the amount withdrawn at any one time should be moderate. 7. In some cases it may be wise to perform several tapplings, drawing off a small quantity each time. 8. The treatment consists in counter-irritation, venesection, and artificial respiration, together with the use of morphin if the cough is severe."

**68. Primary Tuberculosis of Liver.**—Frank reports a case of this lesion and reports as follows: "1. That primary tuberculosis of the liver, though rare, may occur. 2. That the infection may take place by way of the intestine and the portal circulation, the bacilli finding entrance through an ulcer in the bowel (which in this case was at the time of illness some time previous), leaving no trace of the place of entrance into the body. 3. That tuberculosis of the liver may infect the other abdominal viscera and also the peritoneum secondarily. 4. That the process may cause a great increase of the connective tissue in the liver (interstitial hepatitis). 5. That the disease results fatally within twelve months."

**69. Stone and Tumor in the Bladder.**—The co-existence of stone and tumor in the bladder is seldom mentioned in the literature, and Rosenow finds only six articles on the subject. He reports a case and tabulates the recorded cases of this condition. The question of the relation between calculus and nephritis is discussed and the arguments that favor the view of tumor increasing the liability to calculus are given. In 8 cases the calculus was probably secondary to tumor. Tumors are not infrequently incrustated with phosphatic material and villous growths, especially when poorly nourished, and if they become detached, are likely to form a nucleus. The evidence that vesical calculus is a factor in the etiology of tumors is given as follows: 1. In nearly one-half the cases it appears that the stone was primary in point of time. 2. Inflammation of the urinary bladder caused by irritation, other than that produced by calculus, has been known to cause an increased liability to new growths. 3. Tumor of the urinary bladder un-

complicated by stone occurs more frequently in the lower segment, and the probable explanation here favored is the greater irritation of this portion by the chemical and mechanical agencies is the reason for this selection of site. The more frequent involvement of the anterior wall in a series where calculus was present must, in Rosenow's opinion, be ascribed to the influence of the stone. 4. The large number of cases in which the calculus was primary in point of time and the fact that calculi and tumors occur more frequently in the male and at nearly the same age, may be taken to indicate that the calculus was not without etiologic influence in the development of tumor. 5. Since in 90 or 95 per cent. of primary tumor of the gall-bladder, biliary calculi are present, analogy would lead us to expect a somewhat similar relation between stone and tumor in the urinary bladder; hence, the conclusion may be drawn that the etiologic relationship between calculus and tumor is not to be altogether denied. Calculus seems to favor the development of tumor in a larger percentage of cases than tumor favors the development of stone.

**71. The Effects of Color on Bacteria.**—Oliver's conclusions are given as follows: "1. Color-changes both of kind and of intensity take place in and around many chromogenic bacteria when such micro-organisms are placed under different color-conditions. 2. Rehabilitation of chromogenic bacteria into old color environments after having later obtained a new color-value under any particular color-condition, is quite frequently accompanied, sooner or later, with a return of the germ's color-equivalent to that which it primarily held while in its original situation. 3. Differences of color-conditions in pigment-bacteria most probably signify in part relative changes in the various methods of obtainance of sustenance, peculiarities in the kind and ratios of foodstuffs, and irregularities in the character of resulting excreta; each species of color-bacterium exhibiting its chromogenic change in a typical and relevant manner, a behavior that has its determining effect upon the very life of the germ itself. 4. The naming of bacteria by specific coloration is only of value when the actual habitat of the micro-organism is understood. 5. As a postulate conclusion based upon these facts, it is most certain that all living faunal and floral color-changes of true objective type are expressions of biochemic peculiarities taking place in and around such organisms—a mere difference of molecular motion as it were in part dependent upon the relationship existing between active life force and co-existing conditions."

**73. Diabetes Mellitus.**—Croftan has investigated the self-destruction of blood sugar and has repeated and amplified the experiments of Lepine, Arthus, Krause and others which seem to show that the blood and lymph incorporate an agent that can destroy sugar. Other experiments were undertaken to determine the source and character of the sugar-destroying substance ferment. He finds that this agent is contained in corpuscles and not in serum, and in the white rather than in the red cells; whether in leucocytes or plaques is not determined, and the degeneration of the white cells must occur before the ferment can develop its powers. The question as to the influence of the pancreas is also investigated, and it seems probable that it is in some way connected with the manufacture of glycolytic ferment, and that trypsin has formed this glycolytic ferment is shown by the impairment of the blood. Both the solution of trypsin and the solution of glycolytic ferment can digest fibrin in alkaline solution; they can coagulate certain coagulable solutions; give certain proteid reactions; they are precipitable by dilute acetic acids; they are soluble in water after contact with alcohol; they can form bile-pigment and acids from hemoglobin in the presence of small quantities of dextrose; they lose their power if dextrose is not present, and they possess glycolytic powers in the presence of hemoglobin, lose it in its absence and are rendered inactive by contact with urine, so that neither is normally excreted in the active form by way of the kidneys. In fact, they are so similar, even identical, that they can not be distinguished by any known method. Until proof to the contrary is forthcoming, we are justified in considering the glycolytic ferment of the blood and tissues to be none other than trypsin. The question

of what causes pervert glycolysis and reduces the sugar-destroying powers of the body is not easy to answer, but Croftan concludes that pancreatic fluids play an important part in the function. While we can not assume pancreatic disease in all cases of diabetes, it is possible that functional diseases of the organ may exist during life, that leave no anatomic trace and that may have this effect. The recent discovery by Opie in regard to the frequent occurrence of degenerative changes in the islands of Langerhans give a certain experimental basis to such a hypothesis. Some therapeutic suggestions are offered as regards the treatment of diabetes and indications as to the increased glycolysis by supplying glycolytic ferment, and the following measures promise some success: 1. The infusion of chyle or of blood from a healthy animal. 2. The injection of leucocyte extracts. 3. The injection of trypsin. 4. The injection of vegetable glycolytic ferments. The experiments were made on animals that had been rendered diabetic by the extirpation of the pancreas; the reduction of sugar in the urine was observed to ensue in some of the cases from the injection of lymph, though there was a later increase. The leucocytes of the lymph seemed to be active in affecting the glycolytic action for a certain period, and after a while, the glycolytic ferment contained in the cells of chyle injected had disappeared and an increase of sugar followed. The effects of the blood injections were less marked; the injection of vegetable ferment with glycolytic powers has not yet been attempted, and the results of experiments with trypsin will be published later. The extreme toxicity of trypsin proves its greater power of altering the course of normal processes and when carefully tested and its safe dosage determined, it may be found of value in the treatment of diabetes.

**74. Ureteral Anastomosis.**—Nicholson reviews the various methods of operation for uretero-ureteral anastomosis and uretero-cystostomy, reports the general results from what has been done in this line and discusses the question of anastomosis of severed ureters with other organs, such as the bladder, uterus, etc. As regards uretero-intestinal anastomosis he concludes it is not a permissible operation, though the Maydl operation elaborated by Peterson may in future give better results. Little need be said as to the sites of ureteral implantation other than that the bladder, the skin, vagina, etc., all have disadvantages that make them practically out of the question.

**80. Congenital Lens Displacement.**—From his experience with reported and other cases, Brose would treat ectopia lentis: 1. By trying to secure satisfactory vision by properly adjusted lenses. 2. Failing in this, he would determine by the help of the mydriatic and a stenopaic disc whether a small iridectomy will give satisfactory vision—and, if so, perform it. 3. Especially if the patient is under 30 years of age, he would do a discession operation. Over 30 years of age it is better to extract the lens, on account of the danger of secondary glaucoma after discession. As a rule, he instructs the patient from the beginning that this condition has a tendency to grow worse with time, and that if the sight should rapidly fail or the eye become painful, he should report at once.

**87. Rickets from the Obstetric Standpoint.**—Bacon calls attention to the importance of rickets in girls in producing serious pelvic deformity and causing obstetric complications during the child-bearing period, illustrating it by reported cases. The disease is one of infancy, but its effects manifest themselves in adult life, and while we are not in possession of data of infantile rickets, the number of pelvic deformities due to this may be estimated from statistics kept up in various obstetric clinics. We know that pelvic contraction occurs in 10 to 20 per cent. of all women. There is, however, no agreement as to the relative frequency of contraction due to rickets and that due to other causes. Nevertheless, the great importance of rickets as an etiologic factor is admitted by all. He specially calls attention to the importance of early diagnosis. Unfortunately, there are no marked signs for the parents to observe and the physician may have a child under observation for some time before his attention is called to this. Chronic diarrhea should lead us to be on the lookout for it, so should backwardness in teething, sitting and walking. A special sign

of importance which may be mentioned is the well-known beading of the costo-chondral junction. The epiphyseal enlargement of the lower ends of the radius of the ulna, thickening of the bosses of the parietal and frontal bones of the skull and the symptom of head sweating which is so common in rickets should also excite suspicion. There are two considerations of importance: 1. Control of the disease process as soon as possible, which is generally managed by careful dieting and hygienic measures. Frequently we find children on a starvation diet of diluted milk. The other is the care of the child to prevent pelvic deformity and so far as we can learn orthopedists have not considered this phase of rickets. Pelvic deformity is too often neglected, because it is hidden. No doubt there is difficulty in detecting the degree and presence of this deformity. Whether it is possible for practitioners to devise any kind of apparatus to relieve the trunk pressure on the sacrum is left for the orthopedist to decide.

97. **Hernia.**—The points specially presented by Holmes are: 1. That congenital defects are far more commonly the prevailing features in hernia production than has been supposed. 2. Nature protects us from these protrusions by an oblique canal, by an oblique internal ring, by a valve-like oblique flap of peritoneum, and by oblique pressure of the viscera, which actually tends to prevent protrusion. 3. Hernia existing, we should imitate nature; by making a new canal and a new internal ring; and by our methods of suturing so as to render them oblique; the new internal ring being the point of resistance, should not only be buttressed as directed by MacEwen and others, but the parietal peritoneum should be sewed to it above and below, and the new canal should have incorporated in it the floor of the old canal. 4. The aponeurosis of this external oblique muscle is used by nature as a point of counterpressure, and should therefore be sutured in front of the cord and not behind it. The ideal operation for the radical cure of inguinal hernia is still a surgical desideratum.

99.—See abstract in THE JOURNAL, xxxvii, p. 995.

100. **Pelvic Suppuration.**—Pryor holds that as an operation to prevent suppuration and check septicemia, vaginal section stands alone; as an operation of purely evacuative character vaginal section is the operation of choice; and as a procedure seeking removal of the uterus and both tubes, vaginal operation is far superior to abdominal section, except where high abdominal complications are found. For the removal of one purulent set of adnexa, there is no operation equal to abdominal section, and the vaginal operation is not to be thought of. He asks whether pelvic suppuration can be prevented and how. He finds that iodine compounds kill the streptococci, but it still remains for some one to discover the agent that will destroy the gonococcus without injuring the pelvic tissues.

101. **Vaccination.**—Hauenstein argues for the humanized virus as preferable to the bovine virus; he says the claim of some practitioners against the latter is absurd and hints that the epidemic of smallpox all over the world at the present is due to the adoption of this form of vaccine. He thinks the humanized virus will gain in favor and become more general.

106.—See abstract in THE JOURNAL of January 18, p. 197.

107. **The Antistreptococcus Serum.**—The causes of failure of the antistreptococcus serum are credited by Leudeking to: 1. The polymorphism and variability of streptococci. 2. The fact that few septic processes in man are pure, unadulterated streptococcus infections. 3. The usually tardy and late employment of the remedy. 4. The inertness of many of the sera that are on the market. He reports several cases of the use of this serum with advantage, and holds that the early administration of a recent serum in fitting cases of streptococcus infection will prove life-saving. Early intervention in erysipelas and in middle-ear suppuration gave good results. In puerperal infection matters are not so simple, but if the streptococcus pyogenes is the agent, the early treatment should bear good fruit. In any case of abscess of the brain, empyema of the chest, or a purulent exudate in the peritoneal cavity, the serum has no application. Its employment would be irrational, at least until after proper surgical help had been obtained. In the author's experience the injection of serum has

no special dangers. He has met with urticaria and painful joints, accounted for by the large bulk of ingested foreign serum. It is not seen to affect the circulation or respiration. We should watch the kidneys. We should learn properly to apply a good preparation and should give it early in proper cases.

108. **Free HCl.**—Bleyer has investigated the effect of different foods on the production of free HCl in the infant's stomach. He finds from these data that foods containing little or no albumin to utilize the HCl and yet encouraging its production will produce hyperacidity with the usual symptoms of continued vomiting, unremitting hunger and wasting. In absence or deficiency of acid we find intestinal disturbance. He calls attention to the advisability of examining carefully the condition of the gastric juice in every case of infectious enteritis and where HCl is lacking to carefully detract the caseins until sufficient HCl is permitted to exist in the stomach to stay the invasion. When hyperacidity is present, on the other hand, and every food has been tried, when the vomiting is persistent and excessive, and especially with the more delicate foods, then we may increase the caseins, double or treble them, and give the hydrochloric acid a chance to do its physiologic duty.

109. **Diphtheria.**—The rules followed by Saunders in the management of diphtheria are given by him as follows: 1. In all cases exhibiting an exudate or a pseudo-membrane in the faucial mucous membrane, administer pilocarpin at once, in doses large enough to excite its physiologic action. When there is the least suspicion that the case is diphtheria the diagnosis should be settled and antitoxin employed without delay. The dose of antitoxin should be large enough to neutralize all the toxins in the blood and an excess that will neutralize all that may occur in the circulation the following week. A sufficient dose must be given at once and need not be repeated. For a mild case 1500 units may be given, a case of moderate severity should receive 2000 units and a severe infection from 2000 to 3000 units. Special attention should always be given to the antitoxin. If only old serum can be obtained, the least concentrated should be chosen, so that more can be injected, and allowance must be made for the deterioration. A serum that is two months old should be regarded as only about one-half the strength that is marked on the vial. Even when the temperature drops to normal and the membrane begins to be cast off, the pilocarpin should be continued for one or two days in diminished doses, stimulating the leucocytes and hastening convalescence. If the case comes under treatment after the fifth day pilocarpin should be used with caution, on account of the danger of heart failure. Other medication is rarely necessary, except possibly an initial purgative of calomel. Tonics are indicated during convalescence. He believes that applications to the throat can do no good. The fear which many of the profession entertain for pilocarpin is groundless.

110. **Infant Feeding.**—Zahorsky emphasizes the fact that in placing an infant on any food, we should bear in mind that a period of adaptation may be necessary for its proper digestion and assimilation. This period varies in length from a few days to many weeks, depending on a great variety of factors. The idiosyncrasy of the child should be considered. Some can not digest casein or cow's milk and others can not ingest fat. Observations indicate that in the presence of an active gastric juice with a strong percentage of hydrochloric acid caseinogen is well digested. The great susceptibility towards intestinal bacteria and bacterial products in infants is mentioned and inquiry should be made as to the bactericidal power of infants' foods. With our present knowledge we should watch this, but much has yet to be learned. Babies fed on condensed foods and milks are especially susceptible to intestinal infection. Our knowledge of the effects of foods on intestinal peristalsis is also important, and we know that starches are constipating, while fats and sugars are laxative. Beyond this there is not much that is definite. He finds that whey almost invariably increases the number of passages and intestinal irritability, while casein is constipating, as pointed out by Holt. Hence its withdrawal in certain forms of diarrhea is contra-indicated. The question of osmosis is also con-

sidered. Should all food constituents be in solution before absorption takes place? The lesson is plain, in the modification of milk, the osmotic pressure should always be adjusted so that it approximates human milk. The effects of inorganic salts in the food ingested is a matter of importance, though they are usually ignored in the modification of milk. He lays down certain therapeutic principles by which the feeding of infants must be governed, as follows: "1. Normal osmotic pressure should be restored when a deficiency of the diffusible substances is present in the food, by the addition of salts. 2. The electric conductivity of the fluids depends on the presence of inorganic molecules, foods poor in this (as albumen water) should be enriched by the addition of salts. 3. In the process of metabolism, sulphuric and phosphoric acid is formed by oxidation from the tissue proteids, and an adequate quantity of basic radicles must be present in the blood to neutralize these acids. 4. It is known that citrates exist in the milk, possibly other compounds may be found which also contain a metal in combination with an organic compound. Certain dried and heated foods probably do not contain these free bases in sufficient quantity. 5. Sodium chlorid must exist in all foods, but as to the other salts we are yet in the dark."

133. **Artificial Anus.**—Tuttle performs an operation for artificial anus by making an incision one inch above and one and a half inches inside the anterior superior spine, parallel with the fibers of the external oblique, and separating these fibers with a dull instrument. The internal oblique is similarly treated, the wound is held open and the fascia transversalis and the peritoneum incised in the line of the original incision. As soon as the peritoneum is opened, the patient should be placed in the Trendelenburg position and the edges of the wound grasped with fixed forceps to prevent the membrane being stripped off the abdominal wall in subsequent procedures. The wound should be enlarged so as to allow the introduction of the entire hand for thorough exploration, and if a temporary artificial anus is advisable, the rectum is traced upward to the sigmoid flexure, which is grasped and dragged out through the abdominal wound. If the anus is employed to give functional rest to the parts, or for the local treatment of inflammatory diseases of the lower end of the intestinal tract, it should be made in the lowest portion of the sigmoid that is healthy. If it is intended as a preliminary to extirpation or resection of the rectum, it should be made in the highest loop of the sigmoid in order to allow the operator the greatest latitude in dragging down the gut in the operation. After determining the site, the loop of the gut should be drawn well out of the abdominal wound, and a glass rod four inches long should be passed through the mesentery beneath the gut, its ends resting on either side of the wound. Care should be taken to avoid the blood vessels of the mesentery. The gut, being then held above the skin, is fastened at the corners of the wound by chromicized catgut, passed through the skin and peritoneum of the abdominal wound, then through the peritoneal and muscular wall of the gut and finally through the peritoneum and skin of the opposite side of the wound. These are all the sutures required. The abdominal muscles draw together and effectually prevent any protrusion of the small intestine. Small pads of iodoform gauze are put under each end of the glass rod and the whole is dressed with protective tissue covered with absorbent cotton or gauze held in position by an abdominal bandage or adhesive straps. Unless urgency requires it, the intestine should not be opened for twenty-four or forty-eight hours. For gaseous distension the use of a trocar may be advisable. In opening the intestine no portion of its circumference or wall should be sacrificed. It is done by incision in the longitudinal muscular fibers extending from the superior juncture of the abdominal skin down to a point one-half an inch below the rod. At the lower end of this wound a transverse incision is made involving two-thirds of the circumference of the gut. The two little triangular flaps in the upper portion of the loop thus roll upward like dried leaves, the lower flap falls inward and effectually closes the distal seg-

ment of the intestine. The glass rod is left in position from ten days to two weeks, after which time the gut will be so firmly adherent to the abdominal wound that there will be no danger of its sagging down nor of escape of fecal material into the intestine below. This makes an effectual inguinal anus, the entire wall of the intestine is preserved and firm closure is possible without material reduction in the caliber of the canal. In closing the anus the little triangular flaps are uncured by blunt dissection either with the finger nail or a blunt instrument. Their edges and that of the lower flap are then freshened and the T-shaped wound is sutured first by bringing together the mucous membrane with silk sutures and tying the ends inside the intestine. The muscular and peritoneal walls are then brought together by Lembert sutures with fine chromicized catgut. The opening in the gut being thus closed, the latter is then dissected from the attachment to the skin and the muscular wall of the abdomen down to the peritoneum. This membrane is then stripped from the abdominal wall by gentle pressure with the finger or gauze pledgets for about one-half an inch all around the abdominal wound without opening the peritoneal cavity. This loosening forms a loop which allows the knuckle of the intestine in which the artificial anus has existed to drop downward into the abdominal cavity below the muscular walls of the abdomen. The latter are then tied together by one or two silkworm gut sutures and the skin closed as the operator may prefer. He has operated in ten cases in this way; in two there were leakage and small mural abscesses, which were followed by fecal fistulae, which healed spontaneously. In no case was there any tendency to hernia or stricture of the intestines. The operation of closure is practically without any danger, as the peritoneum is not opened and leakage from the wound is therefore always outside of the cavity. In colostomy of the right side, the rod may not be practicable as the mesocolon is frequently too short to drag the gut well outside the abdominal cavity. Here Cripps' method is the one to be followed.

2. **Prostatic Enlargement.**—It is customary to speak of the enucleation of the prostate, and Wallace has investigated to ascertain whether or not it is an anatomic possibility. He has examined a large number of specimens in the Museum of the Royal College of Surgeons and finds quite a difference in structure in the different cases. The increased size of the organ he finds is due in the first instance to increase in the glandular elements. The growth usually affects the greater part of the organ, but often leaves small portions almost unaltered. Within a large area the alteration of the glandular element may be of varying degree, consisting in some cases of small discrete points, while in others well-marked adenomatous lobules occur, usually compound, and may occupy the whole space within the "capsule." The hypertrophy in these cases is therefore best described as an adenomatous hypertrophy, comparable to the adenomatous form of goiter. Next, he considers the nature of the so-called capsule, quoting from Quain's "Anatomy" as to its character, and giving the results of his own examinations. He finds that this capsule is really a portion of the normal prostatic tissue. The stretched and laminated amount of prostatic tissue found after removal will depend on the situation at which the separation has been made. The amount of "capsule" found will depend on whether the separation has been carried through or within the so-called capsule, which is really altered prostatic tissue. It does not seem possible, he says, to enucleate the prostate in its normal state, judging from the examination of the specimens; the upper part of the rectal surface may be cleared of its enucleated fibrous tissue over a small area and the prostate, covered by a thin fibrous layer, exposed. Laterally, these two fibrous layers join together to enclose the lateral plexus of the veins. Immediately within this sheath is a fibro-muscular layer, and by working within this sheath with a blunt instrument the main mass of the organ may be separated from the fibrous covering with more or less difficulty, but leaving a rough and ragged surface without any resemblance to enucleation. The normal organ has no separable capsule. The connection between the prostate and the urethra is even more intimate than between the prostate and its fibrous covering. When, however, adenomatous hypertrophy exists, it is well known that certain forms are enucleable and the surface after may be as smooth as that of most adenomata in the other organs or may exhibit in some cases areas of torn tissue. The readiness of removal depends on the situation of the adenoid masses and the isolation from the surrounding tissue. If they have grown so as to protrude into the bladder, the line of separation, after the incision of mucous membrane, is soon reached and the enucleation quickly carried out. If they lie more deeply a considerable layer of prostatic tissue must be traversed before the line of separation is reached. Then again, the mass may not have become isolated from the surrounding prostatic tissue or only partially so; some tearing may be required. If the quickly growing adenomatous masses were situated near the center of the lobes it is conceivable that they still would have left a considerable zone of tissues between themselves and the urethral wall so that in their removal the urethra may be left intact. There are, unfortunately, some cases of enlarged prostate which do not present any easily separable tumors and any attempt at removal simply means tearing the organ away piecemeal.

4. **The Subcutaneous Injections of Carbohydrates.**—Barker calls attention to a method of introducing compounds into the circulation which may be looked upon in the light of foods, and not merely the innocuous addition to the blood of water that is lost as in the use of saline solution. This is the addition to the normal saline solution of pure glucose. The idea was first obtained from Professor Leunander of Upsala, since which he has used it both in hospital and private practice with much satisfaction. Five per cent. of glucose added to normal saline solution equals .06 per cent. of the total. He finds that a 5 per cent. solution of sugar freezes at the same point as the serum of blood and as normal saline solution and in the language of botanical physiologists is isotonic or isosmotic with the latter and should be indifferent to tissues.

This is a practical fact. The question of isotonic or isosmotic fluids in relation to human tissues is interesting and should always be borne in mind in injecting subcutaneously, but it is only necessary here to remember that fluids (exclusive of corrosives) of the same freezing point as serum are isotonic and produce neither pain nor other change in the tissues in which they are injected. He has largely employed the saccharo-saline solution both in preparing exhausted patients for operation and supporting them during and after the latter. Thus far he has limited himself to 25 grams in twenty-four hours as advised, equal to a liter of 5 per cent. solution and has never seen any sugar in the urine. The mode of its employment is given as follows: "An ordinary aspirator needle of about 1 mm. in the transverse section of its lumen attached to 3 feet of rubber tubing, and with a glass funnel at the other end, is all that is necessary. This apparatus is, of course, carefully sterilized by boiling, and is filled with the sterilized and warmed saccharo-saline fluid; the needle is introduced under the sterilized skin of the arm near the axilla, and the funnel is raised 2 feet, when the transfusion is found to proceed easily, as a rule, until the whole half liter is seen to distend the subcutaneous tissues of the arm and axilla. In preparing, say, for a gastro-enterostomy in an exhausted patient, I do this with 500 c.c., morning and evening if possible, for some days before and up to the time of operation; and on the table again another 500 is injected. Possibly more might be used, but for the present I have been using only the half liter at a time. Again, for days after, while the stomach only receives a limited amount of food and fluid, the same course is pursued. The effect of this treatment has been uniformly good as regards pulse, general strength, and relief of thirst. There is another effect which I think ought to be taken into account in septic cases; for example, appendicitis with septic peritonitis. This is the increased secretion of urine which is rendered possible by the free use of saline injections. We believe that some, if not all, of the toxins in such cases are eliminated from the system by the kidneys. If this is so the presence of abundance of water in the body ought to render the work of the kidneys easier. The toxins would be excreted in more abundance if there were plenty of water to be excreted and in greater dilution. The saving to the kidneys in eliminating dilute poisons rather than concentrated ought to be great, and we ought to see less of renal complications. In a case of very extensive peritonitis following on gangrenous epityphlitis I recently gave subcutaneously half a liter of the fluid mentioned above morning and evening for a fortnight, with, I believe, good results in many ways. But in the preliminary treatment the operation and after-treatment of exhausted patients, the use of the saccharo-saline subcutaneous infusion is beyond doubt of great value, and ought to be more widely known and practiced. A concentrated solution is now made for me sealed up in glass capsules, which can be diluted to the proper strength in a moment with the corresponding amount of boiled water. Such capsules can be carried about for every serious operation and will, I believe, in the future be found of much use."

**8. Pulmonary Tuberculosis.**—In this first lecture Roberts covers the subject of the causation, etc., of thoracic phthisis. He protests against the modern tendency to regard all questions relating to phthisis too exclusively as a scientific study, regarding no opinion as valuable or authoritative unless it emanated from the pathologic laboratory. We can not settle questions entirely by laboratory studies. The pathology of phthisis, that is, its special microbic origin, is well established, though other pyogenic organisms have their share in producing the disease. He thinks too much prominence is given to the contagion of consumption and this has a material influence on social, commercial, professional and practical life. Actual experience does not bear out the public fear which has been roused on the subject. He does not, moreover, seem entirely hopeful as to the extermination of tuberculosis. The vitality of the organism and its general distribution is too great. The various methods of infection are discussed. He thinks there is an exaggerated idea of direct infection and the experience of Brompton Hospital, with which he is connected,

bears out this belief. Still there are occasional instances which seem to point very strongly to it. Auto-infection of the lungs may occur from tuberculous infection anywhere else and a latent focus is very often its cause. Heredity, he believes, has more to do with the subject than modern teaching would seem to indicate, but he would not wish to have people think that because they came of sound stock they are out of danger. Diathesis and temperament are also mentioned. People of scrofulous diathesis have certainly a predisposition in a marked degree to tuberculosis. The temperament does not seem to have much to do with the disease, nor has he been able to associate it with any particular facial physiognomy. Persons of robust type and apparently excellent health sometimes may be subject to the disorder. The various causes acting on the general system are reviewed, including insanitary conditions, deficiency of proper nutriment, intemperance and general debauchery, occupation, conditions which cause a more or less constant drain on the system, such as rapid childbearing, prolonged lactation, menorrhagia, and chronic diarrhea, and lastly, mental depression from causes of various kinds, such as worry and overwork. Each of these is discussed in detail. Traumatism is not infrequently the cause. Alcohol is a notable cause, and he suggests that excessive smoking may be a factor. He lays some stress on the excessive cough, which he thinks has a damaging effect on the lungs, and excessive use of the voice may predispose to phthisis. He has met with cases where hemoptysis resulted from a definite and powerful strain in running, swimming, etc., and from a blow on the chest in persons apparently healthy, and from various conditions, such as pneumonia, chronic bronchitis, pleuritic conditions, pressure on the trachea, etc. Whooping cough, measles, grip, etc., and their well-known relation to phthisis, are mentioned; it occasionally follows enteric fever and other acute diseases. Congenital syphilis sometimes predisposes. As a secondary event it may be associated with diabetes, prolonged indigestion or anything affecting the consumption or assimilation of food, chronic cardiac disease and various nervous disorders. He believes, however, that the idea of some authorities that gouty predisposition is hostile to tuberculosis, and that when the disease occurs among gouty patients its course is much modified and makes but little progress and, as a rule, tends to obsolescence, may be correct. There is a sound foundation, he believes, for these statements. The combination of causes in most cases should be considered. It is often not possible to refer the onset of thoracic disease to any distinct and recognizable exciting cause. He would warn against the modern tendency to ignore altogether the old-fashioned ideas as to the danger of getting wet, chilling, exposure to cold, wind, etc. In conclusion he says he does not share in the extraordinarily hopeful views now so widely entertained and freely expressed as to the final eradication of this terrible scourge. Still we can do a great deal to better matters, and the prevention of infection is of first importance. He would like to see more stringent measures taken as regards the habit of spitting, etc.

**9. Staphylococcus Serum Injections.**—Wright has investigated the subject of the use of staphylococcus serum in cases of furunculosis, etc. He says if we consider the matter rightly we will see that the process of bacterial inoculation, as applied to a patient who is the subject of bacterial invasion, is in reality a process of temporarily taking away from the patient's power of resistance in view to his receiving back the power with usury. In short, it is the process of trading upon the patient's balance of resistance, and it will be wise to inform ourselves beforehand in regard to the resisting powers of the patient. He gives a report of cases with careful examinations of the blood and finds that there are rather favorable results obtained from his anti-staphylococcus vaccine. It may have some value, he thinks, in abnormal vaccinia, and also in the treatment of old ulcers, sinuses, etc. In inoculation it is important to graduate the doses and so to time the injections as to leave to the infected patient in any negative phase which may supervene after inoculation a sufficient margin of resistance to safeguard him against any generalization of his infection. We may keep in view the fact that patients who have

been suffering from long-continued localized inflammatory processes would seem, so far as can be judged from clinical experience, to have acquired a defensive power such as suffices to ward off the more generalized forms of their particular infections and that where bacterial invasions manifest themselves only under the form of "surface-invasions" the conditions in the interior of the organisms must be assumed to be hostile to the growth of the invading micro-organisms. This suggests the desirability of testing the effect of therapeutic inoculations of sterilized streptococcus cultures in the case of patients subject to indolent and relapsing forms of erysipelas, bearing in mind that the streptococcus has a much greater capacity for generalizing itself in the organism than the staphylococcus. A consideration of these facts also point to the "desirability of determining whether any therapeutic advantage could be derived from the inoculation of the appropriate bacterial vaccines into patients suffering from chronic 'surface-invasions.' There would be opportunity of applying such inoculations in connections with the treatment of bronchitis, ozena, gleet, leucorrhea, and those forms of the bacteriuria which depend upon a bacterial invasion of the mucous membranes of the genito-urinary tract. It would, of course, be necessary in each case, after determining the particular species of invading micro-organisms which was giving rise to trouble, to consider: 1, the question of technique in connection with the preparation of the vaccines; 2, the question as to whether the particular invading micro-organism possessed any power of generalizing itself in the system; and 3, the question of the resisting and reacting power of the particular patient. In connection with the estimation of these last, the methods of estimating the bactericidal power of the blood which have been described by myself and the method of estimating the phagocytic power of the blood which has been described by Major Leishman are, I think, capable of rendering services."

**18. Remote Results of Surgical Intervention in Traumatism of the Urethra.**—Guyon warns against immediate repair of the urethra in case of severe traumatic laceration. The intervention should bear the remote results in mind, and the formation of constricting cicatrices be carefully guarded against. He describes three instructive cases. In two the operation was supposed to be very successful at first. The urethra was resected and defect repaired with adjacent tissues, but the remote results proved disastrous. Autoplasty with superposed flaps, the raw sides facing, proved very satisfactory in the one case in which it was done. The results are still excellent after fourteen years.

**21. Preventive Injections of Antidiphtheria Serum.**—Netter reiterates that preventive injections of serum have a pronounced prophylactic effect and have never occasioned any serious accidents. The only inconveniences that have ever been noted are a transient eruption or a few pains in the joints. Unfortunately, the immunity conferred does not commence before twenty-four hours and wears off by the end of three or four weeks. When children have been exposed, the conditions of the environment determine the necessity for these injections. If they can be kept under surveillance by the physician and the sick child has been isolated from the rest of the family, they are not necessary unless positive results are obtained from the nasal and pharyngeal mucus. But under other circumstances, in schools, hospitals, etc., when a case of diphtheria occurs, the other children should receive these preventive injections. Even in the absence of established diphtheria, in measles and scarlet fever wards, they ward off possible diphtheria infection, which is always serious as a complication of these diseases. Heubner has established that twice the dose of serum is required for a little patient with measles, and the immunity conferred lasts only fifteen days on an average. Richardière's experience is conclusive in this line. During the first 4 months of 1901 2 to 4 cases of diphtheria occurred each month in the measles ward and during the following 6 weeks 19 cases developed. The system of preventive injection of every child entering the ward was then adopted and there has not been a single case since. The dose injected was 5 to 10 c.c. of Pasteur Institute serum. Heubner injects 250 units and 500 in measles. In the few

rare cases in which diphtheria has occurred, notwithstanding the preventive injection, it was especially mild.

**22. Surgery of the Heart.**—Fontan reports 2 cases of stab wounds of the heart on which he successfully operated, and Le Dentu supplements his communication by a summary review of 36 other cases of surgical intervention on the heart which he has been able to collect. One operation was undertaken to ligate an isolated injury of certain vessels of the heart. Four were restricted to immediate or tardy tamponing of the organ, with 3 recoveries. Four were non-penetrating wounds and 3 were sutured. All recovered. Twenty-nine were penetrating wounds and 8 recovered after suturing. Five of the deaths occurred on the operating table. Out of the 38 cases, 16 were restored to health. Laforge has recently reported 17 recoveries under medical treatment alone in 56 cases of wounds of the heart, that is, recovery in 30.35 per cent. But only 6 of these cases were stab wounds. Nietert asserts that more than 90 per cent. of unoperated wounds of the heart prove fatal. Italian names are most numerous on the list of operators.

**23. Superiority of Colpotomy for Treatment of Pyosalpinx.**—Treub recommends colpotomy as indicated in every case of tumor in the adnexa requiring the knife. In case of recurrence, colpotomy must be done again and again, with vaginal hysterectomy as the last resort. In case of a hydrosalpinx recurring after colpotomy, a conservative abdominal operation may be suggested.

**27. Multiple Strictures of Small Intestine.**—Patel states that the cases of attenuated tuberculosis of the intestines causing fibrous hypertrophy and multiple strictures, have always been relieved by surgical intervention, and in many instances permanently cured. In cancerous or pronounced tuberculous lesions the results are merely palliative. The diagnosis is based on the character of the pains and the way in which the disturbances travel a certain path, always the same, the pains and meteorism recurring at each stricture as the contents of the intestine move along. In case of cancer the patient is generally older, the general condition more depressed and bloody stools more frequent than under other conditions. He reviews 103 cases on record with details of operation and results.

**28. Cancer of Cecum and Sigmoid Flexure.**—Gouilloud recently operated on a cancer of the pylorus and found 25 prune-stones and a number of cherry-stones. In another case of cancer of the descending colon he found two fish bones at the point of the cancer. He is convinced that foreign bodies create at points of lodgment some erosion or cicatrix favoring the invasion of the cancer. The frequency of cancer of the biliary passages in persons subject to gall-stones is another argument that supports this view.

**29. Hepatoptosis and Hepatopexy.**—Judet has collected 90 cases of hepatoptosis and notes that lithiasis was evident in 15. He has also observed 3 personal cases in which cholelithiasis coincided with hepatoptosis. Treatment of the former alone frequently cures both. Cholecystostomy results in the fixation of the liver by the adhesions which form. Immobilization of the gall-bladder and bile duct fastens the liver in place, and after they are drained the congestion of the liver diminishes and with it the tendency to displacement. In doing hepatopexy the fundus of the gall-bladder—even when it is sound—should be sutured to the parietal peritoneum and abdominal wall or fastened to the lobe of the liver by adhesions induced by leaving a wick between for four to six days.

**30. Paramyoclonus Multiplex.**—Murri has had occasion to make post-mortem examination of three typical cases of paramyoclonus multiplex within a few hours after death. In one case there had been no other nervous symptoms, but the tremor was exceptionally pronounced. The findings were much the same in all the cases and cause him to assert that multiple paramyoclonus is always the indication of some morbid condition in the region of the fissure of Rolando. Although no anatomic modifications may be apparent, yet its function is affected and improved technique might reveal changes that escape us now. Paramyoclonus is therefore single as to its

anatomic site, but multiple as to its nature. A number of causes are liable to induce the modification in the region which is the basis of the tremor. It is not a morbid entity but merely a symptom common to various affections involving the region mentioned: epilepsy, hysteria, meningitis, peri-arteritis or micro-encephalitis, etc. If the paramyoclonus appears to be essential, it is merely because we are unable to class the facts observed with any of the morbid processes known to date.

**38. Pathogenesis of Eclampsia.**—Blumreich asserts that he is the first to establish by clinical and experimental research that the brain becomes altered during pregnancy and that it responds with convulsions at this time to comparatively trivial irritation. The alteration may be due to the diversion of the blood to the genital sphere or to the accumulation of toxic substances in the blood. Whatever the cause, the fact of this increased excitability of the motor centers in pregnancy explains why eclampsia is so closely connected with pregnancy.

**39. New Conservative Operation on the Testicles.**—Rasumowsky has performed this operation on four patients and found it effective in retaining function, while the traumatism is slight and the technique not difficult. After total extirpation of the epididymis he made an anastomosis between the vas deferens and the rete testis or the commencement of the coni vasculosi. In two of the cases only the lower half of the epididymis was removed and the vas deferens was implanted in the body of the epididymis above.

**40. Cause of Death in Strangulation of Small Intestine.**—Albeck relates experimental and clinical experiences which show that death is not necessarily due to peritonitis in case of constriction of the small intestine. In many cases it is due exclusively to the action of toxins generated in the constricted portion and the afferent intestine above.

**42. Operations on Gasserian Ganglion.**—Among the 15 operations on the ganglion described in this communication from von Bergmann's clinic, is the case of a woman of 73 who had been treated for twelve years for typical right trigeminal neuralgia. After a number of partial operations the Gasserian ganglion was removed as a last resort. The patient died four days later of meningitis and the autopsy revealed a psammoma the size of a nut in the posterior cranial fossa. The tumor surrounded the trigeminal nerve and the auditory and facial nerves were also slightly involved. As nothing suggested the possibility of a tumor in this case, the fundus of the eye had not been examined. Of the 14 other patients 13 are entirely relieved of pain on the operated and all but one on both sides. The neuralgia recurred in another case, but this apparent recurrence may be due to some cerebral affection. Ten of the patients recovered with no ocular disturbances, but a preceding chronic conjunctivitis in 2 cases developed into a corneal ulcer with loss of vision in one instance. The dreaded keratitis is probably due to the lesser resistance of the eye deprived of its sensory nerve. In 2 cases paralysis of the abducent nerve was noted and slight opacity of the cornea persists in one. Lexer concludes from these experiences and from the operations reported in the literature which are appended in tabulated form, that extirpation of the Gasserian ganglion is the last resort for severe trigeminal neuralgia not to be controlled in any other way. It is liable to be dangerous, but in most cases it accomplishes the desired result. The tables show that 33 of the 201 operated on died, but that 156, that is, 93.4 per cent. of the survivors, were permanently cured by the intervention.

**44. Operative Treatment of Brain Tumors.**—Bergmann describes 4 cases of brain tumors and 2 of brain cysts operated on. Only one survived in each class. One of the brain tumors proved to be a diffuse cavernous angioma; the patient was a robust man of 44 and he bled to death on the operating table as the angioma was incised. There are 6 cases on record in which angiomas of the brain have been successfully removed. Bergmann states that as the head is raised during operations on the brain the dura sinks and the tumor becomes more prominent. He advises operating as soon as the diagnosis is certain.

**50. Scarlet Fever Nephritis.**—Baginsky dwells with great urgency on the importance of preventing the development of dropsy as of vital importance for the prognosis of this affection. He states that he was able to ward off severe nephritis in the children seen not later than the fifth day. The scarlet fever is kept under control with baths and wet packs and the little patients are kept in bed, even in the mild and afebrile cases, and limited to a strict milk diet. Hydrops did not develop in any case under this regime nor severe symptoms of uremic intoxication. None of the children had the disease so severely as those outside. He considers milk the best diuretic, supplemented perhaps by one to three pints of an alkaline water each day. Diuretin with or without digitalis may be indicated in certain rare cases and prove extremely beneficial. Hematuria is not so alarming as it appears. If it persists and there are no contra-indications, it can almost certainly be controlled with a little tannin, a tablespoonful three times a day of a 1 per cent. solution. Mild, afebrile symptoms of uremia can be combated with senna for a laxative, warm baths, with moderate sweats afterward. In case of fever a cold pack for one to two hours may precede the warm bath to advantage. Very severe cerebral symptoms indicate local blood-letting or venesection. Three or four leeches can be applied to the head of even very young children and, supplemented by withdrawal of 60 to 120 c.c. of blood, may accomplish marvels. Cold applications to the head during the warm bath are also useful at times. Injections of chloral or inhalation of chloroform can not take the place of blood-letting, but may advantageously follow it. One must be prepared at any moment with measures against collapse. Persisting albuminuria is due to the atonic condition of the renal vessels, and usually subsides spontaneously when the child gets out of doors. But if the indications of subacute or chronic nephritis persist and increase, Wildinger or Fachinger water and an easily-digested vegetable diet are necessary, with occasional administration of tannin and, if possible, a change of air to a milder climate or watering place. Under prolonged and systematic observance of these precautions most children can be saved from the threatened chronic nephritis. There will always, however, be a few who are left with a chronic nephritis and persisting cardiac defect as the relics of a severe attack of scarlet fever. In the 75 cases on which this communication is based nephritis was noted in 38, uremia in 18, and 5 of the latter died.

**58. Causes of Infant Mortality in Institutions.**—Schlossmann attributes the low death rate in the Children's Polyclinic and Infants' Home at Dresden to the fact that it is the policy of the institution to supply good breast milk to the children regardless of the expense, which is, on the whole, less than anticipated. Only 53 deaths have occurred among the 207 sick infants, a proportion of only 25.6 per cent., which is very much less than in other institutions of the kind in Germany. The 93 healthy children of the wet nurses are not included in the figures. None of these children contracted any severe disease during their stay at the institution.

**62. Growth of Colon Bacillus in Milk.**—Cazzolino reports that comparative tests showed that human milk is far less favorable as a culture medium for the colon bacillus than milk from the cow, goat or ass. The growth of the bacillus is very much checked from the 14th to the 48th hour in human milk, while it flourishes exuberantly in the other kinds. Human milk does not become as acid as the other kinds under the influence of the bacillus.

**65. Embolism of Superior Mesenteric Artery.**—Sievers describes the case of a patient taken suddenly sick with violent pains in abdomen, moderate meteorism, nausea and slight vomiting and death in twenty-nine hours with the clinical picture of intestinal occlusion and collapse. The case terminated before the hemorrhage into the intestines could be voided.

**70. Substitution of the Bromids for Salt.**—Hondo has found that when the minimum of sodium chlorid is ingested and the bromids are administered, the bromin is eliminated much more slowly and in much smaller quantities than when the patient receives the usual proportions of salt in his food.

**74. Simple Means of Locating Foreign Bodies in Brain by Radioscopy.**—Stamm locates the foreign body on the principle of geographical location by parallels of latitude and longitude. He uses for the purpose a narrow strip of flexible sheet metal provided with holes 1 cm. apart. Small nails are inserted in these holes, the points projecting outward, the heads held in place with wax. This strip is placed on the skull, starting from the root of the nose and passing to the base of the skull behind. A bandage of gauze is then wound around the head. The points of the nails pierce the gauze and the latter holds the metal strip immovable. The radiograph is then taken and the strip is then changed to a transverse position and another radiograph taken, the location of the foreign body each time being marked on the skull and its position in regard to the number of the nearest nail. The nails can be removed as convenient for the patient to rest his head. As the strip is radiographed with the skull the pictures can be compared and serve for future reference.

**77. Treatment of Sepsis.**—Wernitz is enthusiastic in praise of his method of rinsing out the body in case of severe sepsis, by slow, protracted irrigation of the intestines with a .5 to 1 per cent. saline solution injected under weak pressure. The reservoir is lowered from time to time to allow the fluid to flow back out of the intestines. The reservoir is then filled with fresh fluid and the irrigation continued. He maintained these injections twelve out of the twenty-four hours in one case of very severe puerperal sepsis. About five liters of urine were voided by the patient during this time. The temperature rose whenever the injections were suspended and fell again when they were renewed. Four were given the next day and the patient entered upon convalescence. The intestinal tract is kept clean by this constant flushing, and its secreting and excreting functions promoted, while the patient sweats copiously. This sweating is merely the overflow of the fluid arriving in such quantities and does not depress the organism. The patient ceases to sweat when the irrigation is suspended. The vascular system is not overloaded as by subcutaneous injection, although about one or two pints are absorbed in the course of an hour. He states that the results of this simple but tedious procedure were marvelous in a case of puerperal sepsis, one of acute peritonitis and two of septic abortion, which is the list of his experiences to date.

**84. Castration by Application of Steam to Uterus.**—Pineus recommends atmokausis as a simple and effective method of abolishing the menstrual function in cases of incurable affections in which the patients are otherwise doomed to a speedy decline. He describes two cases thus treated. One was a young consumptive, a ii-para, the other in Bright's disease, a iv-para, 32 years old. Both had had extremely severe post-partum metrorrhagia at their deliveries, and the indications for avoidance of future pregnancies were vital. The patients were at the prime of the procreative age and the suspension of the procreative faculty and also of the monthly loss of blood was an indispensable condition for long survival. This was accomplished without pain or danger by the application of steam at 115 and 112 C. for a minute in the second case and at 110 for forty seconds in the first, repeated later for forty seconds. No narcosis, no discomfort nor disturbances of any kind were noted. Menstruation has not occurred since in either case. The uterus is completely atrophied and obliterated above the internal os. The function of the endometrium of the fundus is destroyed, but the cervix is intact, and it is possible that a cervical menstruation may still occur.

**85. Posterior Parametritis an Intestinal Affection.**—Mueller asserts that the troubles known as posterior parametritis, periproctitis, pathologic antelexion, peritoneal adhesions, etc., distinguished by the "uterine syndrome," are generally the result of an affection of the rectum at the point where it is enclosed by the utero-sacral ligaments. They very rarely proceed from the uterus itself.

**89. Toxinemia.**—Kaminer noticed that Ehrlich's iodine reaction of the leucocytes, which does not occur in normal blood, seemed to occur in connection with bacterial processes. He

has therefore been studying it in rabbits and guinea-pigs after inoculation of bacteria. He found that the reaction was more intense when the bacterial toxins were injected instead of the bacteria themselves. The only exceptions were the bacillus of fowl cholera which produced no effect, and tetanus toxin. Diphtheria toxin induced a marked reaction and this difference between the action of these two toxins is interesting. Another point established was that it was impossible to obtain the reaction in animals immunized to a high degree against diphtheria. On the other hand, after the iodine reaction was apparent, it was impossible to save the animal by serum treatment. The iodine reaction can probably always be obtained in man when a sufficient number of bacteria or quantity of toxin is circulating in the blood. There may possibly be some connection between the reaction and the leucocytosis observed in appendicitis abscesses. It may aid in the diagnosis of bacteremia and toxinemia and thus prove of much clinical importance.

**91. Bone Charcoal as Substitute for Iodoform.**—Frommer has been testing bone charcoal which A. Fraenkel has been advocating for the dressing of wounds. The results of his tests were unfavorable.

**92. Gallstone Ileus.**—Karewski points out that the gallstone in the intestines causes an irritation and reflex contraction which may induce the severest symptoms of ileus. The stone may pass along and cause the same symptoms at another point, or if the contraction subsides it may be harmlessly voided. In some cases the irritation induces fatal paralysis of the intestines. The irritation from the stone may lead to perforation and peritonitis. In these cases the stone may be evacuated in some perforating abscess or cause the formation of extensive adhesions with chronic stenosis of the intestines. The stone may dig a diverticulum in the wall of the intestine. In most cases of gallstone ileus the diagnosis has been retrospective, at the operation or autopsy or after the stone has been voided. Even a presumptive diagnosis is impossible in the absence of previous indications of lithiasis. When there is a history of this condition and gallstone ileus is diagnosed, some other cause for the ileus may be disclosed by the operation, such as necrosis of the small intestine, the result of kinking, as in a recent case in his experience. Women are more frequently affected than men, and the subjects are usually over 60 years of age. As the obstruction is generally in the upper portion of the small intestine, after severe symptoms of total occlusion have developed, gas and feces may still be voided from below it. The high location of the obstruction also renders fecal vomiting one of the first symptoms. Gallstone ileus is the only form of obstruction in which fecal vomiting may coincide with natural discharges. The copious vomit contains bile with fecal matters from the small intestine. Another important differentiating point is that the general health does not suffer as in case of ileus from other causes. This is probably due to the fact that the intestine is still slightly permeable and that the circulation of the part involved does not suffer to such a degree. The pulse is more regular and the pains less violent on the whole. The meteorism is less pronounced and less in proportion to the higher location of the obstruction. High obstructions afford the worst prognosis, and thus we are compelled to resort to surgical intervention as soon as it is established that medical measures have none or only transient effect. The more certain the diagnosis of gallstone ileus the more urgent the indications for operation. Only the rapid subsidence of the severe symptoms justifies the postponement of the intervention. Körte lost only 2 out of 7 patients thus operated on. One of these died from collapse and the other was at the seventh day of the ileus and peritonitis had already developed. Even if the stone becomes dislodged it is liable to cause dangerous injury on its further passage through the intestines. Incipient peritonitis is no contra-indication to operation. But the latter may prove ineffective if the intestine has lost its elasticity by too long delay. The operation is alone able to decide the diagnosis—it will perhaps save the patient when a gallstone ileus has been erroneously diagnosed while in fact other irremediable conditions exist.

**93. Specific Treatment of Typhoid Fever.**—Petruschky has been treating typhoid patients for two years with minute doses of dead typhoid bacilli, which he calls "typhoin" for convenience. It keeps for three or four weeks. No inconveniences were ever observed. He injected .5 to 1 c.c. twice a day for three days, gradually increasing to 3 c.c. He first partly fills the Pravaz syringe with a mixture of 5 parts phenol and 8 parts sodium chlorate in 1000 parts distilled water. The typhoin is then drawn into the syringe and the injection is made in the thigh or calf. After the three days of treatment the temperature begins to fall and returns quite or nearly to normal by the end of three more days. In every instance the severity of the disease was mitigated during the treatment. The pulse and sensorium improved and the tongue began to clear up. He found that this treatment was ineffectual when the typhoid was complicated by pneumonia or other severe affections, or was in an advanced stage when treatment was commenced. He observes that not every typhoid culture is adapted for the purpose. He intends to manufacture the typhoin on a large scale.

**95. Results of Surgery of the Kidneys.**—Schmieden reports the tabulated details of 184 operations on the kidney performed by Schede. Five of the 18 cases of malignant tumors have been permanently cured.

**98. Orthopedics of the Ovaries.**—Rose applies this term to an operation performed in two cases. The ovary was found sound but in an abnormal position which had caused severe pains and a tumor-like protuberance. The ovary was restored to its normal position and the abdomen was closed without opening the ovary. Both patients were permanently freed from their disturbances.

**103. Laceration of Intestines from Horse's Kick.**—Riegner has observed fourteen fatal cases of this traumatism and reports one patient who was cured by prompt operation. The success in this case was probably due to the empty condition of the intestines at the time. He urges not to defer the operation on account of shock.

**112. Operative Intervention in Gastric Hemorrhage.**—Kaupe reviews the cases of such intervention which have been published and concludes that the results certainly encourage further attempts in this line, although success is by no means certain, especially if the patient's strength is waning from long-continued hemorrhage from ulcer. Operation should be prompt and must be individualized for each case. Besides the methods commonly in vogue, Witzel has recently been successful in a case of this kind by ligating the large afferent blood vessels without opening the stomach. He found the arteries very much enlarged when the stomach was drawn out. The dilatation seemed to be almost an aneurysm at one point, distinguished further by adhesions, evidently corresponding to the site of the ulcer on the inner side of the stomach wall. He therefore ligated the afferent gastric artery to right and left, and closed the abdomen without further intervention. All hemorrhage was arrested at once, and the patient has been in apparently perfect health during the two years since.

**116. Surgical Treatment of Spasm of the Cardia.**—Cahen describes a typical case of spasmodic contraction of the cardia. An elastic sound could be introduced into the stomach, passing the obstacle, but it was impossible for a single drop of fluid to pass it. There was not a trace of free hydrochloric acid in the stomach then or after the patient had been relieved by gastrostomy. The condition was much improved by retrograde continuous application of the sound, although it proved impossible to keep the cardia completely in repose on account of the swallowing of saliva which accumulated above the contraction in the esophagus. A stout drain tube was introduced through the fistula and left a day at a time. This aided in stretching the cardiac orifice and allowed feeding by the mouth to be resumed. The patient was a previously healthy married man, 35 years old, who became nervously excited over various worries and commenced to vomit frequently. Symptoms of spasm of the cardia soon developed, treated as above described. The stomach fistula healed spontaneously, and for three months his troubles seemed at an end. After this interval his old

symptoms reappeared in a mild form whenever he was worried. He was frequently compelled to leave the table and vomit what he had eaten, but he could then return and finish the meal in peace. He has learned to introduce the sound himself and returns to the physician every ten to fourteen days, when he experiences difficulty in eating. The esophagus is then rinsed out. A slight resistance is still noted at the cardia when a thick sound is introduced. Cahen thinks that this spasm of the cardia is similar to vaginismus in its nature, and may be symptomatic or idiopathic. The former or reflex variety is more apt to yield to treatment than the idiopathic which occurs in nervous persons without any local inciting cause.

**122. Experimental Transplantation of Kidney.**—Ullmann's successful transplantation of the kidney in dogs has attracted much attention. He exposed the carotid artery and jugular vein over quite an extent and applied a ligature or clamp on each side of the wound. They were then severed and a tube of magnesium slipped into the stump of each. The kidney was then ablated and the renal vein fitted over the stump of the jugular and the renal artery over the carotid. The clamp was then removed from the carotid artery and at once the blood poured into the kidney. The secreting function continued undisturbed, evidenced by the dripping of urine from the ureter, the stump of which projected through the wound. The physiologic function continued only five days in each case as the animals scratched the spot and induced irritation which obstructed the ureter.

**124. Destruction of Albuminoids in Liver.**—Töpfer excluded the liver in various ways in his experimental research, and reports that the liver alone is unable to decompose the albuminoids. When the liver circulation is cut off from the intestinal circulation the albuminoids remain unchanged.

**125. Treatment of Epityphlitic Abscesses in Douglas' Pouch.**—Pendl reviews 12 cases of this kind operated on at Hochenegg's clinic, and 4 in his own experience. The mechanical occlusion of the rectum by a large abscess in Douglas' pouch causes symptoms which simulate those of generalized peritonitis or invagination. Differentiation is only possible by digital exploration of the rectum. When the abscess is not recognized and evacuated, general sepsis or pyemia may result from its perforation into the peritoneum. It has been stated that these abscesses occur in 30 per cent. of all cases of appendicitis. Attempts to evacuate them through the abdomen may transform a simple into a complicated case with general peritonitis. The simplest and most effective means of intervention is through a sacral or parasacral incision. A rubber drain can be left for ten days and the patient can be dismissed by the fourth week with a small granulating wound in the gluteal furrow as the last trace of the intervention. By this method the peritoneum does not need to be opened. There is no danger of hernia nor of injury to the intestines from the drain. The rectum tolerates it without inconvenience of any kind. No severe hemorrhage has ever occurred by this method. Eight of the patients were between 9 and 13 years of age, 4 between 16 and 21. Three died from pre-existing sepsis.

**129. The Oculo-Pupil Sensory Reflex.**—Varady applies this term to the reaction of the pupil to sensory stimuli such as contact, heat or electricity. Stefani and Nordera have recently been studying it on healthy subjects. The pupil dilates gradually after a single brief stimulus and then suddenly returns to its original size. If the stimulus is prolonged the pupil first dilates and then contracts to a smaller diameter than at first, then it dilates again and gradually contracts once more. The reflex differs from the light reflex principally in that it takes place much more slowly. The reflex is also soon exhausted and it proves impossible to repeat it. For clinical purposes the first dilatation and subsequent contraction is sufficient for the study of the reflex. The stimulus found most effective in tests on 50 subjects was a needle prick, usually in the malar process. The result is more striking in a weak or moderate light. Prompt response to the needle prick shows that there is no organic anesthesia of the part pricked. It is most marked in subjects with a mobile pupil and occurs in cases of functional distur-

ances in the sensibility the same as in healthy persons, that is, it is present in some and absent in others. It may persist in *tabes* after the reaction to light is lost. In case of anesthesia of organic origin it is impossible to elicit the reflex, but this is only decisive when it can be induced on the sound side.

**133. Vaccination in Prophylaxis of Pertussis.**—Pocchi had vaccinated a large number of infants just before an epidemic of pertussis developed. He noticed that only one of these infants contracted the disease, although all were more or less exposed to it. The one child affected had a very brief attack. He vaccinated a number of older children who were known to be in the stage of incubation, and was impressed by the mildness of the disease when it developed. He noticed, however, that children who had been vaccinated the year before were not immune.

**136. Treatment of Gonorrheal Affections with Guaiacol.**—Bocchi reports ten cases of acute gonorrheal epididymitis and orchitis treated with guaiacol, as recommended by Lenz, in a 10 per cent. vaselin salve. The pain is relieved almost instantaneously and disappears permanently after four or five days. The relief of the pain is more pronounced in the more recent cases. Resolution is remarkably prompt under it and other writers have noticed that the temperature was reduced under this treatment. None of Bocchi's patients were febrile. He has also applied it in two cases of traumatic epididymitis with the same success. The simplicity, convenience and efficacy of this guaiacol treatment render it superior to all other remedies in his experience.

**137. Experimental Proof of Internal Secretion of Suprarenals.**—Salvioli withdrew 8 to 10 c.c. of blood from the suprarenal efferent vein of a dog and injected it into the jugular vein of another smaller dog. This experiment was repeated a number of times and in every instance the small dog exhibited the characteristic variations in the blood pressure, respiration and heart rhythm which distinguish the action of extract of the suprarenals. Similar experiments with blood drawn from other veins failed to produce any such effect.

**139. Methylene Blue in Malaria.**—De Blasi administered methylene blue in 100 cases of malaria with complete cure in 62. He found that it was only effective when the parasite had been circulating for some time in the blood. It seemed to have a tendency in pregnant patients to induce painful contractions of the uterus, and he therefore warns against its use during the last two months of pregnancy. He gave from 20 cg. to 2 gm. in the twenty-four hours, after eating.

**142. Tabes Dorsalis.**—De Britto has been making a careful study of eight cases of tabes. Syphilis was denied in three but was evident in the others. He concludes that tabes is always due to two factors, one is a certain vulnerability of the spinal centers, inherited or acquired, which serves as a predisposing cause. The other factor is some occasional infection or intoxication. Syphilis, pellagra, paludism and intoxication from ergot may serve as this occasional cause.

**145. Experimental Appendicitis.**—Nicolaysen has been studying the connection between enteritis and appendicitis by inducing these processes in animals by bacterial infection. He found that the lesions were similar to those of chronic appendicitis in man. The animals fed on bacteria such as are encountered in human appendicitis developed ulcerations and other profound alterations in the appendix when at the same time the intestinal tract seemed to be intact except for the swelling of Peyer's patches. The lesions in the appendix were more pronounced the longer the animals survived after having been fed on the bacterium coli. The most profound alterations were found at the ninth to the fifteenth day. The lesion most frequently noted was a perforating ulceration.

**146. Transplantation of Tendons.**—Bülow-Hansen collected 75 cases of tendon transplantation in 1900. The results were successful in 75 per cent. The results have been even more satisfactory since that date. He describes fourteen cases in detail, treated by transplantation or a plastic operation on the tendons in case of paralysis, Little's disease, etc. He says that some gain can always be attained, and in many instances it

amounts to an actual cure. The circulation of the blood in the parts is much better, warmth substituting the former clamminess of the skin. He uses the finest silk for suturing and applies a plaster cast in over-correction. The sutures in the skin are left for three or four weeks if temperature is normal. The dressings are renewed and left for two to four weeks. Massage is then commenced, combined with gentle resistance exercises.

**145. Polycystic Degeneration of the Kidneys.**—Borelius describes 4 cases of this condition. One was a casual discovery at an autopsy. One ran a latent course until the subject was 70 years old, when he died after a train of symptoms of chronic uremia. In another case the renal tumor developed without symptoms until infection occurred. The fourth case was complicated by renal lithiasis. The diagnosis of polycystic degeneration of the kidney is probable when symptoms of contracted kidney are observed accompanied by enlargement of one or both kidneys. Another type develops with attacks of pain, suggesting calculi. In still another type the symptoms are those of a slowly progressive chronic uremia with palpable tumor in one or both kidneys. In case of unilateral renal tumor it is necessary to exclude all other causes before thinking of polycystic degeneration, but the diagnosis is easier when both kidneys are affected. Lumbar pains and hematuria are frequent symptoms but are not specific. In 3 of Borelius' cases the patients belonged to the same family, father, son and nephew. Others have noticed a family tendency and the frequent coincidence of congenital malformations of various kinds. As cystic kidneys are a *noli me tangere*, their diagnosis is of great importance. In about 25 per cent. of the cases the liver is also affected with cystic degeneration, and tumefaction of this organ may prove a hint for the diagnosis. Functional diagnosis should not be neglected, whenever it is possible. If the daily elimination of urea is below 16 gm., the functional capacity of the kidneys is evidently diminished, and cystic degeneration is probable, but the latter may exist even when the elimination of urea happens to be normal at the time of the tests. In one of his cases the urea was less than half the normal amount, showing that the other kidney was probably degenerated, although only one kidney was palpably enlarged. If this had been removed the results would probably have been disastrous. On the other hand, the proportion of urea remained practically normal in another case, even after extirpation of the degenerated kidney. This result confirmed the previous diagnosis that the remaining kidney was able to substitute the missing organ, although not necessarily entirely sound. Lumbar exploratory puncture may aid in the differentiation. The fluid contents of the cysts frequently contain small concentric bodies similar to the concretions found in the prostate, sometimes rosette-shaped. Borelius does not know of any other renal affection in which these characteristic little bodies are found. Exploratory incision is a serious operation and cost the life of Holländer's patient. Mohr collected 22 cases of extirpation of the kidney on account of polycystic degeneration, with a mortality of 7.

## Queries and Minor Notes.

### THE AUTOMOBILE.

SPOKANE, WASH., April 2, 1902.

To the Editor:—I note in your number of March 22 an inquiry relative to the best power for automobiles for physicians' use. Having had considerable experience recently in the matter of automobiles, I feel that I can without hesitation advise in favor of the gasoline motor, exploded by an electric spark, for the following reasons: First, that it requires less time to start such a wagon than it does to untie and unlauket a horse; second, that it is the least expensive engine and costs but about one-third as much to run as the steam rig which is its principal competitor. Electricity as a motive power for wagons will never be successful from the standpoint of economy, comfort, endurance, etc., until a light storage battery shall have been perfected, also a battery that will not leak power when the wagon is not in use and one that can be charged quickly. Under the most favorable circumstances

It requires from twelve to twenty-five minutes to start a steam wagon, and, in addition to the large quantity of gasoline required for generating steam, a considerable quantity of water must also be used, which can not be easily replaced under all circumstances. In buying a gasoline motor wagon, however, it should be remembered that most all manufacturers are making two distinct varieties of wagons, each for a specific purpose. One is a light rig called a runabout, weighing about eight or nine hundred pounds with four or five horse power, suitable for two persons on light grades or level roads, where there is little or no mud. The other is a heavier wagon, with six or eight horse power, usually containing two seats, called a touring car, costing a great deal more to operate and too cumbersome, noisy and expensive for city work. Bearing all these facts in mind, being careful to go to a well-established manufacturer, it is safe to purchase and use an automobile in the practice of medicine.

Yours very truly,

C. P. THOMAS.

### New Patents.

Patents of interest to physicians, etc., March 18, 25 and April 1:  
 695,470. Syringe. Young M. Milam, Lake Charles, La.  
 695,761. Vaccination shield. Josiah C. Peacock, Philadelphia.  
 695,496. Invalid's robe. Adeline Schermerhorn, Troy, N. Y.  
 695,657. Ozonizer for wounds, etc. Robert F. W. Smith, London, England.  
 695,658. Ozone inhaler. Robert F. W. Smith, London, England.  
 696,158. Atomizing apparatus. Wm. A. Barton, Jersey City, N. J.  
 695,927. Cesium solution. Wm. A. Hall, Bellows Falls, Vt.  
 696,342. Combined face steamer and inhaler. Henry C. Karpenstein, Brooklyn, N. Y.  
 696,105. Disinfectant. Abiel W. Nelson, New London, Conn.  
 696,123. Surgical dressing. Henry P. Weidig, Newark, N. J.  
 696,538. Catamenical bandage. Heinrich Bauer, New York City.  
 696,722. Physicians' examining chair and table. Robert P. Curtis, Columbus, Ohio.  
 696,802. Adjustable invalid mattress. Maggie Dambaun, Des Moines, Iowa.  
 696,728. Syringe. Richard H. Eddy, Providence, R. I.  
 696,441. Bag for remedial applications. Franklin C. Holmes, Chicago.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., March 27 to April 2, 1902, inclusive:

Alexander P. Bacon, contract dental surgeon, relieved from the Department of Cuba, to take effect April 30, 1902, and assigned to duty at Fort Clark, Texas.

Henry P. Birmingham, major and surgeon, U. S. A., to represent the Medical Department of the Army at the Eleventh Annual Meeting of the Association of Military Surgeons of the United States, to be held at Washington, D. C., June 5-7, 1902.

George M. Decker, contract dental surgeon, from the Department of Cuba, to take effect April 30, 1902, to duty at Fort Logan, Colo.

William H. Forwood, colonel, assistant surgeon-general, U. S. A., to represent the Medical Department of the Army at the Fifty-third Annual Meeting of the American Medical Association, at Saratoga, N. Y., June 10-13.

William C. Gorgas, major and surgeon, U. S. A., when his services are no longer required in the Department of Cuba, to proceed to Washington, D. C., and report to the Surgeon-General for instructions; also to represent the Medical Department of the Army at the Fifty-third Annual Meeting of the American Medical Association, Saratoga, N. Y., June 10-13.

William E. Hall, contract surgeon, from St. Louis, Mo., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Jefferson R. Kean, major and surgeon, U. S. A., when his services are no longer required in the Department of Cuba, to proceed to Washington, D. C., and report to the Surgeon-General for instructions; also to represent the Medical Department of the Army at the Eleventh Annual Meeting of the Association of Military Surgeons of the United States, at Washington, D. C., June 5-7.

Frank E. McDermott, contract dental surgeon, former orders directing him to proceed from Webster, Mass., to duty at Fort Crook, Neb., revoked.

Charles F. Smith, contract surgeon, now at Whitehall, Mich., is relieved from further duty in the Division of the Philippines and assigned to duty at Fort Sheridan, Ill.

Arthur C. Stokes, contract surgeon, from Omaha, Neb., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Engene R. Whitmore, lieutenant and asst.-surgeon, U. S. A., from Fort Sheridan, Ill., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

### Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending April 5:

P. A. Surgeon B. R. Ward, detached from the Boston Navy Yard, and ordered to the *Lancaster*.

Asst.-Surgeon R. A. Bachmann, appointed asst.-surgeon from March 29, 1902, and ordered to the Naval Academy.

P. A. Surgeon E. V. Armstrong, granted sick leave for six months. Pharmacist C. O'Leary, retired from active service April 25, 1902, having reached the age of 62.

P. A. Surgeon D. N. Carpenter, ordered to Naval Hospital, Newport, R. I., for temporary duty.

Asst.-Surgeon W. B. Griffin, detached from Naval Hospital, Newport, R. I., and ordered to accompany a detachment of marines to the Philippines.

Asst.-Surgeon H. C. Curl, ordered to the Naval Hospital, Mare Island, Cal.

Asst.-Surgeon M. V. Stone, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *Constellation*.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended April 3, 1902:

Surgeon H. R. Carter, granted leave of absence for six days from April 1, under paragraph 170 of the regulations.

#### PROMOTIONS.

Junior Pharmacist Charles G. Carlton, to be senior pharmacist from Jan. 13, 1902.

Junior Pharmacist H. E. Davis, to be senior pharmacist from Feb. 10, 1902.

Junior Pharmacist R. F. Troxler, to be senior pharmacist from March 13, 1902.

Junior Pharmacist J. E. Beck, to be senior pharmacist from March 15, 1902.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended April 5, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, March 15-22, 4 cases; San Francisco, March 16-23, 4 cases.

Colorado: Denver, March 15-22, 9 cases.

Florida: Jacksonville, March 22-29, 3 cases.

Illinois: Belleville, March 22-29, 1 case; Chicago, March 22-29, 14 cases; Joliet, March 15-22, 1 case.

Indiana: Evansville, March 22-29, 3 cases; Indianapolis, March 14-21, 21 cases.

Kansas: Wichita, March 22-29, 1 case.

Kentucky: Covington, March 23-30, 13 cases.

Maine: Portland, March 22-29, 3 cases.

Massachusetts: Boston, March 22-29, 15 cases, 4 deaths; Cambridge, March 22-29, 3 cases, 1 death; Lawrence, March 22-29, 1 case; Medford, March 22-29, 1 case; Newburyport, March 15-22, 2 cases; Taunton, March 22-29, 1 case.

Michigan: March 22-29, Detroit, 15 cases; Grand Rapids, 1 case; Ludington, 9 cases.

Minnesota: Minneapolis, March 15-29, 31 cases.

Montana: Butte, March 23-30, 2 cases.

Nebraska: Omaha, March 22-29, 29 cases, 1 death.

New Jersey: Camden, March 22-29, 2 cases; Hudson County, March 23-30, 38 cases, 7 deaths; Jersey City, March 23-30, 25 cases; Newark, March 22-29, 11 cases, 9 deaths; Passaic, March 1-15, 2 cases.

New York: New York, March 22-29, 69 cases, 4 deaths; Yonkers, March 21-28, 2 cases.

Ohio: Chillicothe, March 22-29, 2 cases; Cincinnati, March 21-28, 18 cases; Cleveland, March 22-29, 1 case; Dayton, March 22-29, 1 case; Toledo, March 22-29, 1 case.

Pennsylvania: Lancaster, March 1-29, 3 cases; Philadelphia, March 22-29, 38 cases, 3 deaths; Pittsburgh, March 22-29, 5 cases.

Rhode Island: Providence, March 22-29, 2 cases; Warwick, March 24-April 1, 10 cases.

South Dakota: Sioux Falls, March 22-29, 1 case.

Tennessee: Memphis, March 22-29, 5 cases.

Utah: Salt Lake City, March 15-22, 1 case.

Washington: Tacoma, March 16-23, 4 cases.

Wisconsin: Green Bay, March 23-30, 8 cases; Manitowoc, March 1-31, 20 cases; Milwaukee, March 22-29, 3 cases.

#### SMALLPOX—FOREIGN.

Austria: Prague, March 8-15, 8 cases.

Belgium: Antwerp, March 8-15, 13 cases, 4 deaths; Liege, March 8-15, present, 1 death.

Brazil: Rio de Janeiro, Feb. 9-16, 6 deaths.

Canada: Halifax, March 23-30, 1 case, 1 death; Hamilton, March 1-31, 1 case; Quebec, March 23-29, 11 cases, 1 death.

Colombia: Cartagena, March 10-16, 1 death.

France: Paris, March 8-15, 7 deaths; Rheims, Jan. 5-12, 12 cases, 8 deaths.

Great Britain: Cardiff, Jan. 25-March 8, 1 case; Dundee, March 8-22, 2 cases; Glasgow, March 15-22, 53 cases, 7 deaths; Liverpool, March 8-22, 23 cases, 1 death; London, March 8-15, 450 cases, 81 deaths; Plymouth, March 15-21, 1 case; Sheffield, March 1-15, 6 cases; Southampton, March 8-15, 1 case.

India: Pombay, Feb. 24-March 4, 7 deaths; Calcutta, Feb. 22-March 1, 7 deaths; Karachi, Feb. 23-March 2, 8 cases, 1 death; Madras, Feb. 15-28, 4 deaths.

Italy: Naples, March 1-15, 16 cases, 3 deaths.

Mexico: Mexico, March 9-16, 3 cases.

Russia: Moscow, Feb. 27-March 6, 18 cases, 5 deaths; Odessa, March 8-15, 1 case; St. Petersburg, March 1-15, 15 cases, 3 deaths.

Straits Settlements: Singapore, Feb. 1-15, 1 death.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 9-16, 17 cases.

#### CHOLERA.

China: March 29, Canton, almost disappeared; Sheshing, sporadic; Tung Mun, sporadic.

India: Bombay, Feb. 24-March 4, 3 deaths; Calcutta, Feb. 22-March 1, 158 deaths.

Straits Settlements: Singapore, Feb. 1-15, 7 deaths.

#### PLAGUE.

China: Tsang Shing, March 29, 20 deaths.

India: Bombay, Feb. 24-March 4, 856 deaths; Calcutta, Feb. 22-March 1, 347 deaths; Karachi, Feb. 23-March 2, 84 cases, 62 deaths.

### THE NATURE OF PROSTATIC HYPERTROPHY.

ROBERT HOLMES GREENE, A.M., M.D.

Dermatologist to the City Hospital; Surgeon to the Workhouse and Penitentiary Hospitals; Genito-Urinary Surgeon to the French Hospital.

AND HARLOW BROOKS, M.D.

Pathologist to Montefiore Home and Harlem Hospital; Assistant Curator to Bellevue Hospital; Instructor in Histology and Embryology, Bellevue and University Medical College.

NEW YORK CITY.

In the introduction of this paper the writers wish to state that there is no expectation on their part that they will be able to settle definitely at once all the questions concerning the nature of prostatic hypertrophy. Their object is to place on record a somewhat exhaustive report of the histologic examination of a considerable number of prostates, to mention the results of some clinical experience and to present the conclusions to which the data have directed them. An exhaustive consideration of the theories and data of other observers must, on account of lack of space, be omitted. By confining ourselves to a consideration of the conclusions of observations made during the past five years by those who have had a large amount of material at their command and eliminating those whose conclusions have been made from theoretical considerations, the field to be looked over can be made narrow. From early times until the microscope came into general use the prostatic hypertrophy of the aged was by many considered of inflammatory origin, often thought to have been caused by a preceding urethritis. But for the past twenty years, while the theories as to its nature have been varied, there seems to have been a pretty general consensus of opinion that a true tumor formation of some sort or other was present in the prostatic hypertrophy of the aged and that the prostatitis associated with urethritis found in young men was another affair.

Gouley, who did the earliest serious work on the prostate in this country, claimed that in necropsies of young men suffering from prostatitis who died from intercurrent affections he found conditions apparently resembling those found in the prostatic hypertrophy of the aged. He suggested but did not assert an inflammatory origin in this condition. In his latest publication he considers that inflammation is the cause in some cases but adenoma in others.

The senior author of this article in a paper and discussion<sup>1</sup> calling attention to the frequency of prostatitis as a complication of urethritis from an examination of

216 cases, stated his belief from clinical observation that the hypertrophied prostate of the aged followed prostatitis and again later in a paper read before the Academy, but not published, expressed the same views, giving a list of men who had believed the same thing from clinical observations before the microscope came so generally into play. His views were received at the time with a lack of approval that was, to say the least, discouraging.

At the present time so many observers have noticed the very frequent connection between urethritis and prostatitis that the former may be considered as an etiological factor. Two questions which arise are: what evidence can be brought out at the present time from histologic findings that the nature of prostatic hypertrophy differs to any extent from that found in the past and what new relations, if any, can be shown to exist between posterior urethritis, prostatitis and hypertrophied prostates? Until very recently pathologists almost universally considered prostatic hypertrophy of the aged to be due to true tumor formation and while they differed among themselves as to the nature of these tumors a good many of them thought the tumors consisted of an increase in the amount of glandular tissue, which would be an adenoma; in the muscular tissue, therefore, a myoma; or in the fibrous tissue, a fibroma; or that there existed more or less of a mixture of these three forms.

Referring to important researches published during the past five years, those of Motz, Albarran, Halle and Ciencanowski seem to have been the most deserving of attention. The writers of this article gave the results of some of their observations on the prostate last June in a paper entitled "Fallacies in the Treatment of Urethral Diseases," read before the annual meeting of the American Medical Association in St. Paul.<sup>2</sup> Motz, whose article was the earliest published, arrived at his conclusions from the examination of thirty hypertrophied prostates and his conclusions seem to show that the vast majority of enlargements were of the adenomatous type, that the remaining enlargements were due to a mixture of the glandular and fibrous forms and that the purely fibrous were of a very great rarity. His researches tended to demonstrate that there was no ground for the views held by those who have considered that the changes in the blood vessels played an important part.

Prof. Dr. Stanislaus Ciencanowski<sup>3</sup> reported a most exhaustive study on a large number of hypertrophied prostates as well as studies on the pathology of the bladder and of the kidneys. Whether or not one agrees with the conclusions he reached, every one must agree in praising the exhaustive research, both histologic and

3. Anatomische Untersuchungen ueber die Sogenannte Prostate Hypertrophica und Verwandte Prozesse. *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, Jena, 1900. (Published originally in the Polish in 1896.)

1. Some Observations on the Prostate. *Journal of Cutaneous and Genito-Urinary Diseases*. Read before the American Genito-Urinary Association in 1898.

historical, and give him credit for the excellent plates published illustrating his article. As an indication of the thoroughness of his work it may be stated that the bibliography to which he refers comprises some five hundred names. Briefly stated, Ciencanowski's conclusions were that prostatic hypertrophy was an inflammatory affair, the inflammation extending from the posterior urethra and he suggested blenorrrhagia as a probable cause.

Albarran and Halle followed Ciencanowski by making a most painstaking and exhaustive research of prostatic hypertrophy.<sup>4</sup> Their conclusions were reached from the examination of 100 prostates, which were obtained from men who died from some of the complications of what is generally termed prostatism. Their conclusions—as regards the preponderance of the glandular or adenomal form over that of the myomatous or fibro-myomatous—agree with Motz, whose conclusions were reached after an examination of thirty hypertrophied prostates. They mention Ciencanowski's work, but criticise it by saying that the prostates from which Ciencanowski drew his conclusions were those of young men. While they mention hypertrophied prostate as being due to adenoma or fibro-myoma, using the old terms, so to speak, they do not by any means reject the theory of its being the result of inflammation and while they mention the two different grounds of belief, judging from their language, they seem to lean more towards the latter. It may be interesting here to note that out of the hundred cases they only found one of what they called the purely fibrous form and what has probably been called in the past the purely myomatous form. The conclusion on which Albarran and Halle dwell most emphatically is that in fourteen cases they found a condition which they termed adeno-carcinoma. In other words, they claim that cancer was present in these fourteen cases. They give a history of the cases. Upon reading the histories, two clinical facts seem to stand out prominently in opposition to their theory that those fourteen cases were cancer. One of these facts is that in but one case was there any mention of metastasis. The other is that the clinical histories of most of those cases show that the patients had suffered from their prostatic trouble for many years. Albarran and Halle claim that these are a sort of a tumor midway between the ordinary hypertrophy of old age and true cancer. They make the interesting statement that when a patient who has suffered the discomfort of a hypertrophied prostate for a long time suddenly develops cachexia and dies within a few months without other clinical evidence to account for it, cancer of the prostate is probably present.

While the writers of this paper can hardly agree with the conclusions reached by Albarran and Halle as to the frequency of cancer of the prostate from their histologic findings, as our plates show similar appearances in certain specimens to those shown in their plates and called cancer by them, which we do not consider such, yet we think that surgeons should be grateful to them for directing thought in that direction. Several other cases whose history they give were undoubtedly cancer of the prostate. They leave the impression on our minds that cancer of the prostate is probably more frequent than has been generally supposed and may be held accountable occasionally for cancers in other parts of the body occurring without any history of prolonged irritation. Some such cancers,

therefore, which have been considered primary, may after all be secondary in character.

Regarding the question as to the connection between prostatitis as it presents itself as a complication of urethritis and true prostatic hypertrophy of the aged, it may be interesting to quote here the latest views of Ciencanowski: "To recapitulate, the histologic aspect of all the senile hypertrophies I have studied correspond in many regards to those upon which Mr. Fenger has written apropos of chronic prostatitis of gonorrheal origin. There exists, however, this important difference, that the alterations of the stroma of which I write are much less pronounced in the cases of senile hypertrophy of the prostate and produce the impression of a chronic inflammation of extremely slow evolution." Right here it may be well to examine an argument against the idea that hypertrophied prostate may be of inflammatory origin, which has been brought up in Europe and in St. Paul last June, and that is that any inflammatory processes found in true prostatic hypertrophy are the result of an accidental inflammatory complication such as might come from the improper passage of instruments or the remains of an ancient chronic prostatitis. It may be here stated briefly that one of the main arguments against such a supposition is the fact noticed by Ciencanowski in all his cases that the same appearance was found in all the cases of prostatic hypertrophy examined whether there was any history of the passage of sounds or not. Ciencanowski's reply to the criticisms of Albarran and Halle shows that his cases of hypertrophied prostate were those of old men, some of whom had shown symptoms of prostatism during life and some not, but the same conditions were present in both; and then, again, Ciencanowski, whose views have been confirmed by us, has been able to show the direct connection between the alterations observed, and secondly, the origin of the senile hypertrophy of the prostate.

To quote again from Ciencanowski, "Hypertrophy senile of the prostate has nothing to do with a neoplastic process. The essential cause of this phenomenon lies in chronic inflammation of extremely slow evolution, localizing itself in the glandular tissue, or in the stroma, or in both and resulting in this inflammatory process which resembles from a histologic point of view chronic post-bleorrhagic inflammations and depends in its intensity on its extent and above all on its localization. The appearance of the hypertrophy is much more pronounced if the periglandular inflammation of the stroma is most evident in the center than it is if the interglandular inflammation localizes itself at the periphery of the prostate. The inverse disposition of these lesions does not cause any hypertrophy of the glands and may even cause atrophy." The slow progress of the inflammation we would expect from our knowledge of the slow progress of chronic inflammation in the urethra generally and it should also be borne in mind here that the clinical experience of many men for decades past has led them to believe that hypertrophy of the prostate was of gonorrheal origin, although the clinical experience of some others has led them to dispute it. One argument against the theory that urethritis plays a part in causing prostatic hypertrophy is that in India, where urethritis is common, prostatic hypertrophy is unknown or very rare. An examination of India medical journals and health reports does not seem to bear this out.

4. *Hypertrophie et Neoplasies Epitheliales de la Prostate*, Par M. M. J. Albarran et N. Halle, *Ann. des Mal. des Org. Urin.*, Tome xviii, 1900.

5. *Annual de Malad. des organes Genito-Urinar.*, 1901, "Quelques Aperçus sur le Prostatisme."

To recapitulate briefly, the results of the work done on the nature of prostatic hypertrophy during the last five years by observers who have had the opportunity of forming their conclusions from the observation of a large number of prostates amount to about this:

1. That any former belief that prostatic hypertrophy was due to atheromatous conditions of the blood vessels is erroneous.

2. That the purely myomatous or fibrous form of prostatic hypertrophy is extremely rare, as is being shown by unanimous conclusions, resulting from investigation, by Motz, Albarran and Halle and Ciencanowski.

3. Motz, Albarran and Halle consider that proliferation of the cells of the glandular portion of the prostate, either alone or mingled with changes in the stroma, play the most important part in the hypertrophy of the gland.

4. Albarran and Halle do not dispute the fact that a chronic inflammatory process furnishes the phenomena presented, but lay special consideration on conditions found histologically in a large portion of the prostates examined by them, fourteen out of a hundred, and which they consider are either cancer in the prostate or a sort of a product midway between inflammatory and cancerous tissue.

5. Ciencanowski in his very exhaustive studies of the prostate considers hypertrophy the result of a chronic inflammation of the organ, the original seat of which can always be found if searched for long enough by means of a large number of sections. According as the original focus of the inflammation is in the periphery or in the center of the organ a corresponding form of prostatic hypertrophy or atrophy will be present.

Following is a description of the histologic work done by us on the subject. The exact number of prostates, including normal ones, that have been examined and from which the selection was made on which our conclusions are founded, it is not possible for us to state. The junior author of this paper has for six years been examining all the prostates that a large amount of necropsical work permitted him to obtain. The number would probably run into the hundreds. A hundred or over were collected, including normal ones, for the purposes of the paper read in St. Paul last June. From the total number of prostates which the writers of this paper have been able to gather, a selection was made of all those which showed marked enlargement, in other words, which were apparently abnormal prostates, whether we were able to obtain any history of the cases or not. These enlarged prostates were fifty-eight in number. We consider that they can properly be termed hypertrophied prostates from the fact that under the microscope the same or similar conditions were present in them all, whether they had been removed and we had the history of the case, or whether they were some specimen, of whose history we know nothing. We either have or are able to obtain the history of 19 of the 58.

Six of these have been removed at operation. We believe that in so large a series, selected conscientiously without regard to anything except the presence of tissue augmentation, we have included all usual varieties of prostatic hypertrophy. This condition being most frequent in the aged, we assume that the majority of our specimens have been taken from old men. The process which we have found has been of the same nature in all the cases, the difference being entirely quantitative or of degree. For this reason we state with confidence that our studies have been based on all true types of prostatic hypertrophy. The tissue removed for examination was

always selected from that portion of the gland which showed the greatest hypertrophy. Several sections were taken from a single gland, wherever from the gross appearance of the tissue considerable variation in structure was expected. The notes recorded on each specimen have been as brief as possible, only points directly bearing on the problem under consideration have been touched. No attempt has been made to sub-classify or exhaustively describe the various types of prostatic hypertrophy. The entire study has been made with the idea of detecting the cause of this common condition.

We wish to express our thanks to Dr. B. Lapowski for having first called our attention to the extremely interesting work of Ciencanowski; to Dr. John T. McGowan, who handed to us for the purpose of the paper last spring a collection of some sixty prostates which he had gathered and on which he was carrying on some histologic investigations in connection with Dr. Smith; to Drs. Howard Lilienthal, Frank Hartley, Henry Morton, Raymond Guiteras, Chas. Phelps and George Stewart, each for a prostate which they had removed by operation. Through the kindness of Dr. Charles Peck, six specimens were obtained from the Museum of the New York Hospital, some if not all of which we understand had been removed at operation, about which we have not yet had time to obtain the histories. The Museum of the Carnegie Laboratory, the morgue and various other sources supplied other specimens.

#### HISTOLOGICAL REPORT.

CASE 1.—N. Y. H., No. 3876. Great chronic interstitial increase with obliteration of acini in places, and marked atrophy of muscle fibers. Patches of round-cell infiltration about the acini and particularly in the neighborhood of vessels. In some places structure seems about normal, but acini are generally small and corpora amylacea few. The interstitial increase and obliteration of acini are most marked in the peripheral portions.

CASE 2.—N. Y. H., No. 2121. Acini in central portions are cystic, filled by cells and detritus. Corpora amylacea are fairly numerous. There is generally a considerable increase in the amount of connective tissue with a corresponding decrease in the muscle cells. There are a few areas of small round-cell infiltration about the periphery and occasionally about some of the central acini, but inflammation is mostly represented by the chronic connective tissue hyperplasia.

CASE 3.—N. Y. H., No. 2431. In general the tissue is normal, but in one portion there is intense round cell infiltration which has produced partial necrosis and has infiltrated deeply into the substance of the gland. Acute connective tissue hyperplasia is apparent about these areas, but the remaining portions of the gland are otherwise natural.

CASE 4.—N. Y. H., No. 6446. Moderate distension of acini, some of which are completely filled with detritus and epithelial cells. Considerable round-cell infiltration about some of the acini, particularly in the central parts of the section. In these areas there is an increase in the connective tissue stroma, with a compensatory relative decrease in muscle. Elsewhere the relative amounts of muscle and stroma are normal. Corpora amylacea are few and small.

CASE 5.—N. Y. H., No. 5265. General stroma much increased, particularly about certain acini and ducts where the hyperplastic tissue is in the adult form. Still other acini are surrounded by zones of small round-cell infiltration, in parts of which injection of vessels and true acute inflammatory changes are made out. Corpora amylacea are infrequent, though some of the acini are much dilated.

CASE 6.—N. Y. H., No. 4877. Great enlargement of glandular acini, so that appearance is of large cysts, lined by a layer of usually simple columnar epithelium and filled by detritus, cells and small corpora amylacea. The connective tissue about these dilated acini is increased and occasionally karyokinetic figures are found in the connective tissue cells. Small areas

of small round-cell infiltration are present, particularly about some of the acini. The muscle cells in places have been replaced by hyperplastic connective tissue. The blood vessels are not congested, and show but a very moderate degree of atheroma. Some are surrounded by an adventitia which is more or less infiltrated with small round cells. Apparently, some edema of the tissues is present. This specimen represents what would ordinarily be called a cystic adenoma of the prostate.

CASE 7.—Greatly enlarged middle lobe from specimen in Carnegie Laboratory Museum. The peripheral portions of the gland show a thickening of the connective tissue, particularly about the vessels, where frequent areas of round cell infiltration are also found. Muscle cells have been largely replaced in these areas and the glandular acini and ducts have been compressed by interstitial hyperplasia. The central portions of the middle lobe are made up of much dilated acini, which are mostly filled by epithelial cells, many of which are breaking down. Small round-cell infiltrations are frequent about these acini and connective tissue increase is marked. The blood vessels show slight atheroma. Corpora amylacea are infrequent.

CASE 8.—Museum specimen from Carnegie Laboratory. Great enlargement of the middle lobe. Considerable increase in connective tissue, numerous large fibroblastic cells, moderate small round cell infiltration in patches about vessels. The central acini are much dilated and are filled by broken-down cells and cell detritus. Occasional small corpora amylacea are present in these cystic acini. The blood vessels show slight arteriosclerosis.

CASE 9.—From Museum Carnegie Laboratory. Great middle lobe hypertrophy. Some of the acini are small, being compressed as a result of hyperplasia of the surrounding connective tissue, but most of the acini are enlarged and filled by one or more corpora amylacea, several of which are extremely large. In the immediate neighborhood of such acini muscle tissue has been replaced by fibrous tissue of adult form. Nearly all the acini contain such large bodies. The blood vessels show moderate arteriosclerosis.

CASE 10.—From Museum Carnegie Laboratory. Great hypertrophy of the middle lobe. Quite extensive perivascular connective tissue increase. The acini are widely separated and there is a general connective tissue hyperplasia apparently of perivascular origin. Patches of small round cell infiltration are frequent. The acini are centrally situated, usually widely distended and filled by cell detritus, polygonal epithelial cells and small corpora amylacea.

CASE 11.—Museum Carnegie Laboratory. Hypertrophy of middle lobe. Marked increase of adult connective tissue. The acini are represented by small openings and are compressed by the hyperplastic connective tissue about them. The vessels show marked arteriosclerosis. Such acini are usually filled by polygonal epithelial cells and small corpora amylacea. The interstitial hyperplasia has also resulted in muscular atrophy.

CASE 12.—Museum Carnegie Laboratory. Greatest enlargement in middle lobe. Well-marked connective tissue increase in peripheral portions of gland, showing both old and recent changes. Peripheral acini almost completely obliterated by overgrowth of connective tissue. Central acini distended somewhat and contain cells, detritus and small corpora amylacea. Patches of small round-cell infiltration frequent. Moderate arteriosclerosis.

CASE 13.—Prostate enlarged about one-third, from a man of 53 years. Morgue. Most portions of the gland are normal, but occasional patches of cell infiltration are found, particularly about certain acini which are over distended and contain epithelial cells, the central portions of which have broken down into amorphous material grouped as though forming corpora amylacea. Occasional acini are surrounded by hyperplastic connective tissue which has stenosed their ducts. This is particularly frequent in the peripheral portions of the section. The vessels are mostly congested and show but slight atheroma. The muscle has in some areas been more or less displaced by the hyperplastic connective tissue.

CASE 14.—From morgue. Subject aged 63. Enlarged about

one-fourth. Marked adult connective tissue increase extending in from periphery where acini are almost completely obliterated and where round cell infiltration is almost general. The central acini are cystic, contain detritus, epithelial cells and small corpora amylacea. The walls between these distended acini are much thinned and are almost wholly fibrous. Some of the larger acini contain very numerous corpora amylacea. The vessels show a moderate degree of atheroma.

CASE 15.—Morgue. Quite general interstitial hyperplasia with the result that nearly all parts of the gland show collapsed acini, surrounded by hypertrophied connective tissue. In some places there is considerable inflammatory infiltration, but in other areas this is wanting. 'Connective tissue' hyperplasia in this section seems mostly limited to the periacinous tissue. Corpora amylacea are infrequent and small. The vessels show very little change.

CASE 16.—Morgue. Section is from periphery of gland. Vessels show marked atheroma, one shows endarteritis obliterans. Few acini in section. Considerable connective tissue hyperplasia, displacing much of the muscle tissue and obliterating the glands. No acute inflammatory exudate.

CASE 17.—Morgue. Tissue generally normal. Slight interstitial increase about certain distended acini. The vessels show no abnormality.

CASE 18.—General hypertrophy. From morgue. No inflammatory patches. A few areas in which perhaps there is slight increase in the connective tissue. The acini are not small, but are filled by cells and contain moderate quantities of detritus. Corpora amylacea are infrequent and are mostly small, though a few are found which nearly fill the acini. One border of section shows, however, a quite intense small round cell infiltration, with connective tissue proliferating about it—apparently this is a recent process.

CASE 19.—Morgue. Enlarged one-fourth. Contains an encapsulated whorl of connective tissue which shows both chronic and acute inflammatory diseases. General connective tissue increase, with occasional areas of inflammatory exudate and with apparently general edema, particularly about the enlarged and cystic acini in central portions of gland. Some of these enlarged acini are completely filled by a single great corpora amylacea, others contain several smaller ones. Inflammatory reaction about these acini is abundantly shown. The vessels show a moderate degree of arteriosclerosis.

CASE 20.—Morgue. Enlarged one-half. Great connective tissue hyperplasia, in places obliterating the acini, while in other places the acini are large and distended, probably from obstruction of their ducts. Great inflammatory exudate into periacinous tissue. Numerous and large corpora amylacea, some of which are surrounded by occasional epithelial cells, being otherwise encapsulated by connective tissue. A very marked and decisive specimen, showing all forms of inflammatory reaction. Blood vessels show but moderate atheroma.

CASE 21.—Morgue. Enlarged laterally, diminished in antero-posterior diameter. General connective tissue increase particularly in central portions of the gland, where the process is still active and round-cell infiltration general. Peripheral acini are largely dilated, surrounded by augmented connective tissue and many contain corpora amylacea. Such acini have but few epithelial cells and the walls are almost entirely fibrous and round cell infiltrations are quite frequent in them. Occasional acini contain only epithelial cells and detritus. The blood vessels show slight atheroma.

CASE 22.—Morgue. Slightly enlarged. Acini mostly dilated, filled by epithelial cells, though some contain corpora amylacea. The glandular epithelium shows numerous evidences of proliferation. Some contain several corpora amylacea of moderate and small size. There are occasional patches of round-cell infiltration about the acini, slight in degree. The specimen apparently represents an intra-acinal inflammation which has not extended beyond to any appreciable degree. Blood vessels natural.

CASE 23.—Morgue. Enlarged one-third. Very marked general connective tissue hyperplasia still active but not entirely acute in character. Extensive patches of infiltration in places. Interstitial growth about some acini has almost obliterated

Fig. 1.—Showing an area of small round cell infiltration. This condition is one of the most frequent manifestations of inflammation seen in hypertrophy of the prostate. Section taken from the peripheral portions of the gland. Case 34.

Fig. 3.—This picture may follow immediately on that shown in the previous plate. The inflammatory infiltration is less and is replaced by numerous fibroblasts and newly formed connective tissue fibers. The acinus shown is partly filled by proliferating epithelial cells. Case 55.

Fig. 2.—Showing general cell infiltration, edema and desquamation of the cells of the acini. This stage precedes and induces interstitial hyperplasia. Case 42.

Fig. 4. The plate shows several acini which have become compressed by the production of new connective tissue about them. This has resulted in the atrophy of the epithellum of the acini and finally terminates in complete replacement by hyperplastic connective tissue. From the periphery of the gland. Case 36.

Fig. 5.—Section of a prostatic fibroma. The hyperplastic tissue making up the substance of the fibromatous nodule is clearly defined from the more adult fibrous tissue surrounding it. We believe that conditions similar to this follow the process illustrated in the previous plate. Peripheral part of gland. Case 39.

Fig. 6.—Section from the central portion of a hypertrophied prostate. One of the excretory ducts of the glands is seen to be completely obliterated from the formation of new connective tissue in and about it. Round cell infiltration is present throughout the hyperplastic tissue. The acini in the outer portions of this gland were much dilated, forming the so-called cystic adenoma of the prostate. Case 41.

Fig. 7.—This shows the condition produced in the gland when the ducts become closed as shown in the previous figure. This lesion is commonly known as the cystic prostate, and in the fresh condition the spaces formed by the distention of the acini is filled by a semi-fluid material. Specimen taken from the outer part of gland. Case 47.

Fig. 8.—Section showing dilated acini which are filled by proliferating epithelial cells. This condition in some of its forms may be readily mistaken for carcinoma. Mitotic figures are not present in the cells in the centers of the islands, but are seen in the cells still lodged against the basement membrane, the inference is that reproduction is taking place only in the last mentioned cells. From outer portion of gland. Case 36.

Fig. 9.—Showing the presence of large corpora amylacea occupying the dilated acini. They have apparently formed from the detritus of breaking down cells in such a condition as that pictured in Fig. 8. From the peripheral portion of gland. Case 53.

Fig. 10.—Conditions of this nature result when prostates containing large corpora amylacea become infected. Pus formation is shown in one part of the section and the remaining portions show interstitial sclerosis, atrophied acini and cell infiltration. From central part of gland. Case 52.

Fig. 11.—Showing proliferation of connective tissue about large corpora amylacea when situated in the outer zones of the gland. Atrophy of acini, general infiltration and connective tissue hyperplasia. Case 54.

Fig. 12.—Carcinoma originating in the hypertrophied prostate gland. Case 45.

Fig. 13.—Carcinomatous infiltration of enlarged prostate gland. Case 50.

them, but occasional acini are dilated and these are mostly filled with epithelial cells. In the central part is found detritus, showing evident beginning formation of corpora amylacea. Blood vessels show quite extensive arteriosclerosis, but perivascular connective tissue increase is still more evident. This specimen shows to a very extreme degree a hyperplastic inflammation of the connective tissue with slight involvement of the glandular parenchyma.

CASE 24.—Morgue. Enlarged one-fifth. Acini generally dilated and filled by cells and detritus. Formation of numerous small corpora amylacea in the acini, connective tissue of gland stroma not increased. Blood vessels natural. Lesions are apparently only the distention with marked epithelial proliferation in the acini. Probably represents an early stage of prostatic hypertrophy.

CASE 25.—Morgue. Moderate hypertrophy, very hard. Increase of connective tissue marked, very extensive and general infiltration of small round cells, not only in stroma, but also in acini. Muscle tissue mostly displaced by the hypertrophic connective tissue. Acini which are not involved by cyst formation mostly filled by epithelial cells or detritus. Many acini completely collapsed from the great proliferation of surrounding connective tissue.

CASE 26.—Morgue. Moderately enlarged. Acini largely dilated, contain large corpora amylacea in various stages of formation. Other acini are filled by epithelial cells and detritus. Many are surrounded by numerous but small areas of round-cell infiltration and in the neighborhood of these connective tissue hyperplasia is evident, particularly immediately around such acini, where in some cases the process is well advanced. Other acini appear perfectly natural, and in many places the stroma is also normal, showing regular proportion of muscle and connective tissue and no inflammatory infiltration. Blood vessels show moderate atheroma.

CASE 27.—N. Y. H., No. 2431. Moderate general connective tissue hyperplasia. Acini in general show very little change, except where acute inflammatory process is present. Very intense small round-cell infiltration in peripheral portion, some places of which show pus formation and local tissue necrosis, with in places hemorrhagic extravasation. A true acute and sub-acute inflammation. Few small corpora amylacea.

CASE 28.—Morgue. Moderate general hypertrophy. General connective tissue hyperplasia of chronic form. Acini dilated and filled by proliferating cells. Perivascular connective tissue increase marked. Moderate atheroma.

CASE 29.—Carnegie Museum. Great middle lobe hypertrophy. General connective tissue hyperplasia. Areas of round cell infiltration numerous. Acini are enlarged, cystic and filled by epithelial cells and detritus, with formation of corpora amylacea. Moderate atheroma. Many vessels are surrounded by exudates of small round cells.

CASE 30.—N. Y. H., No. 3878. Moderate general chronic connective tissue hyperplasia, but the most marked lesion is a pronounced infiltration of small round cells, between the connective tissue fibers. In certain parts of the peripheral portion, particularly in the region of the prostatic urethra, this cellular infiltration has become so extreme as to result in tissue necroses and actual pus formation. In places this process has practically wiped out the acini and the infiltrations are found scattered throughout the entire gland. Some of the centrally situated acini are dilated, being filled by cells, and cell detritus. In the most acute inflammatory areas the vessels are congested and a few hemorrhagic extravasations are found in the region of the urethra, otherwise the vessels show only a slight atheroma.

CASE 31.—Prostate operated on by Dr. Guiteras. Greatly enlarged. Great hyperplasia of adult connective tissue throughout entire gland, most abundant about the dilated acini. Areas of round-cell infiltration are common and have apparently originated from or about the acini. Centrally situated acini are much dilated and are mostly filled with epithelial cells or detritus, which has resulted from disintegration of these cells. Some of the acini have apparently ruptured into their neighbors. Corpora amylacea are small and

infrequent, but formation of them is apparently taking place from cell detritus. The vessels show but very slight atheroma in most places and the interstitial overgrowth is clearly not of arterial origin. In some places small round cell infiltration of the septa between the dilated acini is very extreme. Of course where interstitial hyperplasia has been great muscular atrophy has been correspondingly marked.

CASE 32.—Enlarged prostate removed by Dr. Lilienthal. Very marked hypertrophy. General connective tissue hyperplasia, in places with actual formation of fibrous nodules, where all traces of muscle and glandular tissue are replaced by a firm mesh of hyperplastic interstitium. Areas of round cell infiltration are frequent and large and usually bear direct relation to the acini, which are mostly small, being compressed by the connective tissue growth. They are largely filled by cells and detritus. Corpora amylacea are infrequent and small, being found only in the larger acini. The vessels show a moderate atheroma.

CASE 33.—From Carnegie Laboratory Museum. General hypertrophy. Tumor projecting into bladder from middle lobe. Peripheral portions made up of a dense zone of connective tissue containing but few muscle fibers. Areas of small round-cell infiltration are frequent both in the outer and in the central portions. Central portions chiefly made up of greatly dilated acini, filled with broken-down cells and detritus. Frequent areas of inflammatory exudate about the dilated acini. Corpora amylacea frequent but small. Blood vessels normal.

CASE 34.—Carnegie Laboratory. Tumor of middle lobe. General fibrosis. Acini as a rule are atrophied, apparently from the pressure of the surrounding hypertrophic connective tissue. Some of the acini are, however, greatly dilated and are filled with cells, detritus and small corpora amylacea. Numerous areas of small round-cell infiltration surrounded by zones of fibrosis. The walls of the blood vessels are slightly thickened.

CASE 35.—From Carnegie Museum. Prostate measures 6 by 10 cm. Hypertrophy involving all portions equally. Enormous distention of acini which are filled by broken-down cells, detritus and small, but frequent corpora amylacea. Stroma very scant in central portions, but peripheral portions show hyperplastic connective tissue and are almost devoid of muscle fibers. Blood vessels apparently normal.

CASE 36.—From Carnegie Laboratory Museum. Entire prostate enlarged, particularly the middle lobe, which is about three times the usual volume. Walls of bladder hypertrophied and sacculated. Marked general increase of fibrous connective tissue. Muscle fibers are still abundant, but many are degenerated, as though from pressure. Many of the acini are distended with broken down cell detritus, but others are atrophied and show marked increase of the connective tissue about them with resulting complete atrophy of the acinus. In these areas inflammatory changes are very marked surrounding the alveoli. Blood vessels show a marked atheroma.

CASE 37.—From Carnegie Laboratory Museum. General hypertrophy with tumor of middle lobe. Sections of the middle lobe tumor show an incapsulated fibromatous nodule 1 cm. in diameter. This area shows a well-defined capsule of adult connective tissue enclosing acini atrophied or dilated. In either case the lumen is filled by detritus and small corpora amylacea. Blood vessels are numerous and thick walled. Round-cell infiltration about the acini is frequent and it is also present about the small blood vessels.

CASE 38.—From Carnegie Laboratory Museum. Enlarged about four times. Hypertrophy most marked in the left lobe. Peripheral portions made up of thickened and infiltrated connective tissue. In the central parts the acini are either much atrophied or distended. In the latter case the central portion of the acinus is filled with a fine granular debris and the walls are covered by a thin layer of columnar or squamous epithelium. The connective tissue cells show many evidences of proliferation. Muscular atrophy is clearly shown, particularly about the enlarged acini, where more or less inflammatory infiltration is present. Blood vessels show no change.

CASE 39.—Carnegie Laboratory Museum. General hyper-

trophy of prostate and of the walls of the bladder. Very marked connective tissue hyperplasia with general glandular atrophy, particularly where the acini are compressed by the hyperplastic connective tissue. Patches of inflammatory infiltration are present about nearly all of the acini and also about the smaller blood vessels. Small fibromata, highly vascular and evidently of recent origin, are present in places (see plate). Blood vessels slightly thickened.

CASE 40.—Carnegie Laboratory Museum. Great enlargement of the middle lobe with less marked hypertrophy of the lateral lobes. Peripheral portions show marked fibrous increase. Central portions made up of greatly dilated acini, between which thin connective tissue walls intervene. These walls are almost universally infiltrated with small round cells. Blood vessels moderately thickened.

CASE 41.—Specimen removed by Dr. Morton. General augmentation of the connective tissue stroma. Frequent areas of inflammatory exudate. Acini are generally small and are frequently surrounded by zones of infiltration. Walls between the acini are atrophied. Most of the acini contain proportionately large corpora amylacea. Blood vessels natural.

CASE 42.—Carnegie Laboratory Museum. Prostate enlarged about 6 volumes. Abscess cavity in anterior portion 2 cm. in diameter communicating with posterior urethra through dilated duct of prostate. Section taken from portion of gland distant from abscess cavity. The entire interstitium of gland is edematous and is infiltrated with numerous small round cells and plasma cells. This infiltration is most pronounced about the acini, which are filled for the greater part by broken-down cells and by inflammatory exudate. Some of the acini are compressed by the exudate about them. Pus formation is not present in these sections. Under high magnification the epithelial cells of the inflamed acini show frequent karyokinetic figures.

CASE 43.—From Carnegie Laboratory Museum. Moderate degree of general hypertrophy. Muscle tissue almost completely absent and in some portions the glandular elements are represented by spaces lined with a layer of simple squamous epithelium filled by a single large amyloid body and invested by a capsule of hypertrophic fibrous connective tissue. In other portions of the same gland the sections show but very numerous small acini with thin walls, evidently formed by the distention of the acinus by the pressure of its own secretion since the walls of the acini show numerous evidences of distention.

CASE 44.—Carnegie Laboratory Museum. Moderate hypertrophy limited in the lateral lobes. Great general connective tissue hyperplasia. One side of the section shows a few atrophied voluntary muscle fibers surrounded by a greatly augmented endomysium. The acini are large, mostly filled by cells and by corpora amylacea and frequently surrounded by an edematous infiltrated interstitium. The blood vessels show thickened walls.

CASE 45.—Carnegie Laboratory Museum. General hypertrophy, particularly of the middle lobe. Walls of the bladder are hypertrophied and ulcerated. Very marked hypertrophy of the connective tissue with almost complete atrophy of the muscle fibers. Acini for the greater part filled by cell detritus and inflammatory exudate, but in certain of the acini the epithelial cells have taken on very active proliferative changes with the result that they are filled with large epithelial cells supported by connective tissue stroma which has grown in from the walls of the altered acinus. The nuclei of these cells show numerous karyokinetic figures and the specimen is undoubtedly one of carcinoma, originating from the inflamed acini of the gland. Blood vessels greatly thickened throughout the section and in places endarteritis obliterans is shown.

CASE 46.—Carnegie Laboratory Museum. Marked hypertrophy of lateral lobes. The interstitium throughout the entire section is greatly increased, particularly about the glandular acini, where evidences of recent connective tissue proliferation are abundant. The acini are atrophied and contain frequently but a single large amyloid body. Other acini are filled by the epithelial cells and small quantities of detritus. The adventitia of the blood vessels is generally thickened.

CASE 47.—Carnegie Laboratory Museum. Moderate hyper-

trophy. Numerous small semi-pedicated nodular masses project from the surface of the prostate. Marked general connective tissue increase with consequent muscular atrophy. The acini are greatly dilated and are usually lined by a thin layer of simple squamous epithelium. They contain detritus which has apparently remained after the evaporation of fluid. Corpora amylacea, where present, are usually single and completely fill the acinus in which they are lodged. The vessels show marked endarteritis.

CASE 48.—Carnegie Laboratory Museum. Great hypertrophy of the middle lobe. Peripheral portions show a very marked fibroid increase which is of less pronounced degree in the central portions of the gland. The central acini are distended by epithelial cells and detritus. Corpora amylacea are small and frequent. There is a general inflammatory exudate throughout the entire section. Blood vessels normal.

CASE 49.—Carnegie Laboratory Museum. Great enlargement of the entire gland. Small pediculated tumor projects from middle lobe into cavity of bladder. This last portion shows in section almost complete substitution of glandular tissue by dense fibrous connective tissue which encloses frequent corpora amylacea of large size and surrounded by connective tissue only. Blood vessels moderately thickened.

CASE 50.—From Carnegie Laboratory Museum. Moderate hypertrophy involving all portions of the gland. Wall of bladder thickened and the seat of several carcinomatous ulcerations. The connective tissue of the gland is greatly increased and is infiltrated in almost all portions by columns of actively proliferating epithelial cells. A few large corpora amylacea are found situated in atrophied acini and the acini throughout the section are compressed by the greatly augmented connective tissue and by the infiltration of this stroma by cancer cells. Blood vessels moderately thickened.

CASE 51.—Carnegie Laboratory Museum. Moderate hypertrophy of the lateral lobes, great enlargement of the middle lobes. Great thickening of the walls of the bladder. Peripheral portions of the gland show an advanced connective tissue hyperplasia with inflammatory infiltration. Central portions show distention of the acini with atrophy of their walls and formation of numerous small corpora amylacea. Blood vessels moderately thickened.

CASE 52.—From autopsy. Man aged 57. Patient died of meningitis following abscess of the prostate, pyonephrosis and general sepsis. Prostate enlarged about six volumes. Abscess cavity of prostate measuring 2x3 cm., communicating with posterior urethra through ducts of prostate gland. This case gave a history of long standing but "cured" posterior urethritis. Acini throughout entire gland are infiltrated with pus cells. In this exudate are found frequent large corpora amylacea. The connective tissue stroma is greatly augmented throughout, the increase being in adult fibers. There is inflammatory exudate of the entire glandular substance, even where far distant from the abscess cavity.

CASE 53.—From autopsy. Man aged 60. Cause of death acute on chronic alcoholism. Prostate enlarged about one volume. Peripheral portions show a marked increase in connective tissue. The stroma throughout the entire gland is infiltrated with small accumulations of round cells. In the peripheral portions of the gland the acini are greatly dilated and contain very large corpora amylacea. In the central portion of the gland the amount of connective tissue is more abundant and the glandular acini are smaller and are either empty or contain less detritus. Corpora amylacea are numerous, though small. The blood vessels are moderately thickened. In the areas of greatest connective tissue hyperplasia, that is in the central portions of the gland, muscular atrophy with connective tissue substitution is very pronounced. Blood vessels normal.

CASE 54.—From the autopsy of a man aged 53, dead of alcoholism and pneumonia. History of chronic prostatitis obtained. Marked hypertrophy, particularly of the lateral lobes. General connective tissue hyperplasia. Infiltration of small round cells through entire stroma, especially about the acini, which are generally atrophied and contain large corpora amylacea. Blood vessels moderately thickened.

CASE 55.—Specimen removed at operation by Dr. Geo.

Stewart. Patient aged 57. Has had difficulty in passing urine for past ten years. Entered Bellevue Hospital with retention of four weeks' standing. Urine drawn for three weeks by prostatic catheter. When in good condition, operated on by Dr. Stewart. Bloodless specimen weighed 115 gm. Acini generally dilated and filled by proliferating epithelial cells, cell detritus and numerous small corpora amylacea. Several acini are largely filled by pus cells. Inflammation has apparently traveled from these acini to others in the neighborhood. The connective tissue stroma is hyperplastic and contains many areas of small round-cell infiltration. Interstitial hyperplasia has been so marked about certain acini as to produce marked glandular atrophy. This is more observable about the ducts in the neighborhood of the posterior urethra.

CASE 56.—Removed at operation by Dr. Chas. Phelps. Patient an old man who gave typical history of enlarged prostate of long standing. Mass of tissue removed measured 8x7x5 cm., very nodular. Gross diagnosis of cancer of prostate. Entire tissue greatly infiltrated with serum, stroma very edematous and shows exudate of small round cells, occasional leucocytes and many plasma cells. General hypertrophy of interstitium, particularly in region of posterior urethra where there are many evidences of a chronic inflammatory process of long standing with the result that hyperplasia of connective tissue has constricted the prostatic ducts, producing great distension of glandular acini in peripheral portions of gland. Acini about border of gland largely filled with proliferating epithelial cells, cell detritus and numerous small amyloid bodies. Acini in central portions of gland often occupied by single very large amyloid concretions and surrounded by zone of infiltration. The blood vessels show no abnormality.

CASE 57.—Specimen removed at operation by Dr. Hartley. The specimen is divided histologically into two distinct parts. The largest of these is located in the anterior portion of the tissue and extends from the periphery to the central parts of the gland. It is made up of large hyperplastic fibers of connective tissue in which beginning sclerosis is apparent. Numerous fibroblasts are also present and many of the connective tissue cells show karyokinetic figures. Areas of small round cell infiltration are frequent and include occasional plasma cells intermingled with the round cells. The acinal arrangement is wholly obliterated in these portions by the overgrowth of the connective tissue, but in several places multiplying epithelial cells are found, mostly in rows infiltrating between the connective tissue fibrils and in places forming small islands of actively dividing cells. Apparently the epithelial proliferation is a recent process and it probably is developing into carcinoma of the scirrhus type. The histological picture is found only in certain parts of the posterior portions and near the center of the gland. These show an active connective tissue hyperplasia, but the fibers are more of the embryonic type than those found in the previously described portion. The epithelium in this portion of the gland has more of the normal arrangement and though the cells are dividing they do not have the appearance of cancerous growth. The blood vessels show slight thickening. Corpora amylacea are few, found only in the second portion and are small in size.

CASE 58.—Tumor removed from the lateral lobe of an enlarged prostate of an old man at autopsy. The sections show marked hypertrophy of the interstitium, the increase being in adult tissue only. The acini are small and are much encroached upon by the overgrowth of connective tissue about them. Several acini are partly filled by epithelial cells which are largely broken down. The blood vessels are slightly thickened. Corpora amylacea are of small size and few in number.

A review of this series of 58 cases shows that abundant evidences of inflammation are present in every gland. Naturally, the precise character of the inflammatory lesion differed considerably and often a single gland showed several types. The most common lesion noted was interstitial hyperplasia and this was almost invariably accompanied by resultant atrophy of the muscle cells of the gland. Thus, in 41 of the 58 cases, the prostatic hypertrophy was entirely or largely due to increase

of the fibrous connective tissue. A considerable percentage of these cases showed fibroblasts and newly-formed fibers as well as other evidences of recent proliferation of the connective tissue, as shown in Fig. 3.

Thirty-six cases show areas of inflammatory infiltration, usually consisting principally of patches of small round-cell infiltration, though some showed a more extreme change, characterized by the presence of plasma cells and marked edema, as shown in Case 42 from which Fig. 2 was taken. In 5 cases pus formation was present; in 3 of these infection had clearly taken place from the posterior urethra. It is probable that had all the sections been so cut as to include the posterior urethra we should have found that this were even more frequently the case. Nineteen of the 58 cases showed more or less cystic formation. The true character of these cysts and their mode of formation from inflammatory disease of the prostate will be discussed later in the paper. These 19 cases are such as would ordinarily be classified as cystic adenomata of the prostate; that they are in no way adenomata will be shown later. Of the 6 specimens, in which marked proliferation of the glandular epithelium was present, 3 belong also to the cystic prostates. Only 5 neoplasms of the prostate were found. Of these 2 were carcinomata and 3 fibromata. Case 57 also probably represents an early stage of cancerous growth. Neither fibro-myomata, myomata nor true adenoma were present. Atheroma or endarteritis of moderate to marked degree was present in 17 cases.

To recapitulate briefly: in the 58 cases studied all showed evident inflammatory lesions. In 41 the increase in size was entirely or chiefly due to fibrous proliferation, but in 36 inflammatory infiltration played a leading or contributory rôle and in 19 cystic distension of the alveoli was present in sufficient degree to notably increase the size. Six tumors were present, 3 of which sprang from the interstitium (the fibromata, Cases 19, 37, 39) and 3 from the epithelium (the carcinomata, Cases 45, 50 and 57). No cases of true glandular or muscular hypertrophy were found.

Interstitial hyperplasia is then found to be the most frequent cause of hypertrophy of the prostate. That interstitial increase after adolescence is the result of inflammatory disease is so generally recognized that it is not necessary to discuss this point at this time. Nevertheless, since it is the most frequent factor in the production of prostatic hypertrophy, it must be considered in its relation to this condition at some length.

It is our purpose to discuss later the origin of the process so we shall assume a condition of acute or sub-acute prostatitis as a starting-point. In all organs, acute or sub-acute inflammation gives rise to interstitial hyperplasia; small wonder, then, that the process becomes marked in the prostate, an organ abundantly supplied with blood vessels and highly cellular connective tissue. The interstitial hyperplasia, coupled with more or less edema and cell infiltration, always associated in so highly vascular a tissue, gives rise to the acute prostatic hypertrophy, such as is found in the young. With a cessation of acute inflammation following a removal of its cause and normal reaction on the part of the tissues of the organism, interstitial hyperplasia should cease and retraction and atrophy follow from the sclerosis of the fibers, as the embryonic tissue takes on the adult form. Such a result does follow in favorable cases of prostatitis in the young and healthy, and, as the sclerosis of the newly-formed tissue continues, the atrophic or small hard prostate follows to a greater or less extent, always

provided, however, that this same fibrous sclerosis does not excite secondary changes in the glandular epithelium. But in the middle aged or old man, particularly where more or less general or arterial disease exists, resolution and healing do not so readily follow and instead of cessation of connective tissue hyperplasia the condition becomes chronic. With the increased fibrosis, consequent thickening of the walls of the veins and lymphatics follows and chronic congestion is added to the factors tending to prolong and increase interstitial hyperplasia, edema and inflammatory exudation. So it happens that in the enlarged prostate of the aged, acute and sub-acute proliferations are found mingled with the thickened masses of adult sclerosed connective tissue. As an inevitable result of this overgrowth of stroma, atrophy of the smooth muscle cells follows. This may be of greater or less degree, greater if the inflammation partakes more of the acute type where parenchymatous degenerations are most rapid, less if the process be more chronic.

As a result of this overgrowth alone, when continued for months or years, considerable prostatic hypertrophy may follow, but to this process is added secondary changes, taking place in the glandular tissue, which increases the enlargement of the prostate.

If the fibrosis be most marked in the peripheral portions of the gland it results in encroachment upon and fibrous thickening of the walls of the alveoli which finally become compressed and obliterated—Fig. 4. If the hyperplasia be most marked in the central portions of the gland or about the ducts this results in obstruction or occlusion of the ducts—Fig. 6. After occlusion of the ducts continued secretion on the part of the glandular epithelium causes a distension of the acini and alveoli, producing the familiar cystic adenoma of the prostate—Fig. 7. When now desiccation or condensation of this secretion follows, corpora amylacea form—Fig. 9. Even though the duct be partly pervious the formation of these bodies and the inspissation of the secretion, mingled with desquamated epithelium, renders normal drainage of the alveolus impossible and cysts of considerable size result. If absorption through the walls be marked and the surrounding fibrosis sufficiently active a single amyloid body may later be found surrounded by a thick connective tissue capsule, perhaps still lined by a layer of atrophied squamous epithelial cells—Fig. 11.

Although three small encapsulated fibromata were found in our series of specimens, and though their structure is identical with that of fibromata found elsewhere, we are still loath to classify even these as true neoplasms of idiopathic origin. When the proliferation of stroma is especially active about a group of acini, the actively growing fibroblasts compress these gland sacs more and more until, as shown in Fig. 4, atrophy of the epithelium takes place and fibroblasts grow in, filling up the space, producing a nodule of highly cellular young connective tissue enclosed by a capsule of more dense adult fibers—Fig. 5. Undoubtedly a true fibroma may originate from the prostate gland, but our study of these specimens leads us to the above explanation for the formation of the prostatic fibromata seen by us.

Albarran and Halle have recently called our attention to the frequency with which carcinoma originates in hypertrophic prostates. While we concur with these authors in their general statement, we do not accept as cancer most of the cases which they picture and classify as such; of this more later. Careful study of our three cases of hypertrophied prostates, in which carcinomatous

growth was present, we believe throws some light on this very important subject. In two of our cases cancerous invasion of the walls of the bladder was present, but after careful study of the gross and microscopic specimens we feel justified in concluding that the growth was primary in the prostates. In our cases, the cancer involved but a limited part of the enlarged gland and the usual interstitial and inflammatory infiltrations of the ordinary enlarged prostate were present—Figs. 11 and 12. For these reasons we believe that the cancer had attacked the glands subsequent to their hypertrophy, as is undoubtedly the case with specimen 57. It is universally admitted that the chronic or sub-acute inflammation of glandular stroma tends toward the production of malignant epithelial proliferation. Surgeons and pathologists admit that these conditions predispose toward cancer of the mammary gland and so in the enlarged prostate we have a chronic interstitial proliferation compressing and irritating the alveolar epithelium; with these most favorable conditions we can only express surprise that cancer of the hypertrophied prostate is not more frequent.

In a certain number of enlarged prostates we find an epithelial proliferation of an entirely innocent character. These are those cases in which dilatation of the glandular sac is followed by a proliferation of the epithelium which finally completely fills the gland sac and gives rise to an appearance frequently resembling carcinoma—Fig. 8. It is this condition, in certain of its modifications, which we believe Albarran and Halle have in some cases mistakenly called cancer. Six of the specimens studied by us show this lesion in its most exquisite type. Ordinarily it can easily be distinguished from carcinoma by the fact that the cells resting on the basement membrane are distinctly columnar and that those in the central portions of the cell islands show many degenerative alterations of both nucleus and cytoplasm without karyokinetic nuclear figures, except in the cells resting on the basement membrane. When, however, such acini become greatly compressed by the interstitium about them, they resemble cancer very closely, but this new growth should not be diagnosed unless it be found that the proliferating epithelial cells are invading the tissues about the acini—Fig. 13. We fully agree with Albarran and Halle, nevertheless, in their statement that primary carcinoma of the prostate is much more frequent than generally recognized, and it is highly probable that the hypertrophied organ is more than seldom the site of unrecognized primary carcinoma. Undoubtedly, true adenoma of the prostate may exist. We have, however, not yet seen a case and we contend that the condition ordinarily described as such is not adenoma and that its origin is due to the occlusion of the glandular ducts after the process described above.

Atheroma has been considered by some as an etiological factor in the production of prostatic hypertrophy. Moderate to extreme atheroma was found in seventeen of the cases of this series, but in each instance it was accompanied by other and more pronounced lesions more directly bearing on prostatic hypertrophy. It is now generally admitted that when atheroma is found in the prostate it only represents a local manifestation of a general condition and that it is just as frequent in normal or atrophic prostates taken from men of like age as in the hypertrophied gland.

The question has doubtless occurred to many of our readers, if these inflammatory changes noted by us may not be secondary or accidental in character, caused by the

prostatic hypertrophy and not its cause. We believe that this legitimate question can be answered in the negative. We have endeavored to show in the above examinations that the increase in size of the glands was either immediately or secondarily due to the direct inflammatory exudates or to the reaction on the part of the tissues to these processes, i. e., interstitial hyperplasia.

Granting that our observations in this series of specimens is correct, the origin of the inflammation is yet to be ascertained. In certain of our cases (30, 52, 55, and 56) the sections apparently indicated that the primary inflammatory process had originated about the posterior urethra. Had all our sections been chosen with the determination of this point in view, it is probable that a larger percentage would have shown this condition. But at best, such deductions from the histologic picture are uncertain and more or less speculative. In our opinion clinical evidence is much more trustworthy. It will hardly be questioned that prostatitis most frequently results from, or follows, posterior urethritis, and posterior urethritis is usually primarily or secondarily of gonococcic origin. Asserting as we do, however, that prostatic hypertrophy is the direct result of chronic prostatitis, by the same chain of clinical evidence we are forced to the conclusion that it follows posterior urethritis from whatever cause. For the reasons stated above chronic proliferative prostatitis is more frequent in the aged than in the young.

From our study of prostatic hypertrophy we believe that the usual story of this disease is as follows: Given a posterior urethritis, infection of the ducts and alveoli follows. This is accompanied by inflammatory infiltration about the walls of the infected sac. Following this inflammatory exudate (Fig. 1), which may involve large portions of the gland, fibroblasts and plasma cells appear and acute interstitial hyperplasia becomes inaugurated, as shown in Figs. 2 and 3. The changes which now follow depend largely on what portion of the gland is involved. If the hyperplasia be most marked in the peripheral portions, the acini become compressed and the epithelium atrophies (Fig. 4) and from such acini small fibromata may result—Fig. 5. If the process be more slow and infiltration still active, the condition shown in Fig. 6 may follow. Should the fibrosis be most marked about the ducts or the glands, constriction of these tubes may produce pictures like that shown in Fig. 7, which may be followed by that shown in Fig. 9. Now, if fibrosis be marked about the acini the condition shown in Fig. 11 may happen; on the other hand, acute inflammation with pus formation may take place, as seen in Fig. 10. If proliferation of the alveolar epithelium be excited, pictures like that of Fig. 8 are produced and if this irritation result in malignant cell proliferation true cancer may form (Fig. 12) finally with carcinomatous infiltration of the interstitium—Fig. 13.

This work on prostatic hypertrophy has purposely been founded on histologic findings only, for the reason that in the early days, when the study of prostatic hypertrophy was necessarily purely clinical, or aided only by gross observations or rude microscopic methods, the general impression was that the disease was inflammatory in nature. This fact has already been stated in our introduction. This idea held until, after incomplete sporadic microscopic studies, a theory was formed, founded purely on the histology of the disease, that prostatic hypertrophy was a true tumor formation and

idiopathic in its origin. Nearly all text-books on general pathology now give this view and the greatest of pathologists have favored the theory either by copying what others have written or by confining their personal observations to a few specimens only. Serious histologic studies of the hypertrophic prostate have not been numerous and for this reason, if for no other, we are much indebted to the recent, most careful and thoroughly scientific study of Ciencanowski, who has fully demonstrated by his histologic observations that hypertrophy of the prostate is an inflammatory disease.

This study was taken up by one of us with the idea of disproving the statements of Ciencanowski and satisfying himself of the truth of the idea expressed in nearly all works on pathological anatomy. The result has been a complete conversion to the views of Ciencanowski, whose conclusions we endorse fully, as far as our work has covered his field. We therefore take no credit to ourselves for originality of thought or discovery, leaving all credit to the clinical observers who first advanced the theory and to Ciencanowski who first fully and finally proved its truth.

We may briefly state our conclusions as follows:

1. Prostatic hypertrophy of the aged is the result of chronic prostatitis.
2. It most frequently arises from chronic posterior urethritis, of whatever cause.
3. True neoplasms of the prostate are rare and are not concerned in the production of prostatic hypertrophy.
4. Carcinoma is apt to occur in the hypertrophied prostate as a result of the chronic inflammatory process.

## SARCOMA OF THE UTERUS.

D. S. FAIRCHILD, M.D.

Professor of Surgery, Medical Department Drake University; Surgeon to St. Joseph's Hospital.

CLINTON, IOWA.

During the present year a lady 65 years of age came under my care presenting the following history and symptoms. The mother of several children, she had enjoyed good health until about two years ago, when she began to be troubled with constipation and pain in the lower part of abdomen and a sense of weight and pressure in the pelvis. These symptoms gradually increased. About six months prior to coming under my observation the symptoms became more acute, when she had, according to her statement, a discharge of fluid from the bowels. This gave her a measure of relief, but soon the same chronic condition she had previously suffered from appeared and continued on with some increase in severity until she came under my care in August of last year. A physical examination revealed the uterus to be uniformly enlarged to two or three times its normal size and appeared to be firmly impacted in the pelvis. There was no discharge from the organ and the symptoms seemed to be largely due to pressure. The general condition of the patient appeared to be good, although she had lost in weight and was somewhat anemic. This could be accounted for, in part at least, on the ground of constipation and impaired digestion.

The age of the patient and the fact of the growth appearing after the menopause suggested malignancy, but the absence of positive symptoms of cancer indicated the possibility of a non-malignant growth. Assuming the probability of an enlarged and myomatous uterus I opened the abdomen. The peritoneum was very much thickened and there was found a considerable quantity of free fluid in the abdominal cavity. The abdominal

wound was made sufficiently large to admit of a free examination of the uterus after the intestines were walled back by large abdominal pads.

The bladder was normal in appearance. The uterus was uniformly enlarged and occupied the usual position in the pelvis and reached upwards to a point corresponding to a uterus enlarged to the fourth month of pregnancy. The anterior surface of the uterus presented a grayish-white appearance, and fluctuated on palpation. The sigmoid was well crowded over to the left. The uterus was firmly adherent on its posterior surface. Masses of new growth extended out on either side to the ovaries and broad ligaments. It was at once apparent that we had to deal with a sarcomatous uterus and that any attempt to remove it would involve a dangerous hemorrhage with small prospect of getting all the diseased tissue. I could not see my way clear to secure safe hemostasis on either side of the uterus, and having in mind the certain and speedy return of the disease in such cases, I determined not to expose the life of the patient in the useless attempt to remove the organ. I opened the cyst on the anterior surface of the uterus just sufficient to explore the interior, about one ounce of clear fluid escaped, revealing a very red and irregular velvety surface. The thick cyst wall became flaccid when the fluid escaped, which enabled me to surround the three-quarter inch incision with a purse-string suture slightly inverting the edges, thus closing the opening completely. I now reinforced the purse string with a few additional sutures. Catgut was used in both instances. I folded over the sutured surface a strip of iodoform gauze, which I allowed to extend out of the lower angle of the wound, inserting a secondary suture to be tied when the gauze was removed on the sixth or eighth day; otherwise the wound was carefully closed. On the eighth day the gauze was removed, followed by the discharge of some serous fluid and the secondary suture tightened. The patient was discharged and returned home, a distance of 150 miles, in good condition at the end of the second week.

It was my impression that the less we disturbed the diseased organ the better it would be for the patient. I doubted the wisdom of opening the cyst, but the unusual appearance of the organ and the desire to discover the condition inside the cyst led me to do so.

My personal experience with diffuse sarcoma of the uterus is extremely limited, but the literature of the subject does not give much warrant for operative procedures when the disease has advanced so far as to make the diagnosis easy before an operation is undertaken. In early cases where scrapings have revealed the sarcomatous nature of the disease better results may be expected, or in somewhat later cases, when the disease is clearly confined to the organ and the tying off can be easily accomplished without leaving any part, an operation may be warranted. But when the disease has plainly spread out over the broad ligaments, even to a moderate extent, no good can be accomplished.

A recent examination shows that the growth has rapidly increased since the exploratory operation and her general health has correspondingly declined and the fatal termination is not far off. I realize the fact that a diagnosis as to the character of a morbid growth without a microscopic study lacks in scientific accuracy, but the clinical importance of arriving at a conclusion at the operating table was, in my judgment, of the utmost importance. If the disease was malignant I ought to have removed it; if non-malignant, I am very sure I

would have shortened her life. I recalled the special features in the history of the case, that a few months previous to the operation a quantity of fluid had escaped from her bowels, giving her for a time some relief. This was no doubt due to the emptying of a cyst lying in contact with the sigmoid. I took into account the general appearance of the mass, the free fluid in the abdominal cavity, the adhesions and the extension of the growth on to broad ligaments. I had never before seen a cyst sarcoma of the uterus or a sarcoma which had undergone cystic degeneration. But I was so firmly impressed with the idea that I had one before me that I had no hesitation in acting on the theory that it would be much better for the patient to let it alone. What the antecedents of the growth were I do not know. But it is quite probable that a fibro-myoma involving the fundus had existed for perhaps a long time which had more recently undergone cystic and sarcomatous degeneration. An important diagnostic symptom was absent, namely, a uterine discharge; but it may be assumed that the endometrium and sub-mucous tissues were not involved. However, there was no distinct tumor and the organ appeared to be uniformly enlarged, a condition which would seem to favor the probability of such a general involvement as to lead to hemorrhages. It may be observed that recently a moderate loss of blood has occurred on one or two occasions. Since the operation, and for some time before, she has suffered severe pain in the abdomen, has lost much in flesh and has become very anemic.

The development of a diffuse sarcoma of the uterus after the menopause is much less frequent than carcinoma, but that it does occur late in life is well established, and it has particularly been observed to occur as the result of degenerative changes in fibro-myomas, which have no doubt remained stationary for a long time. When these growths, which appear to give no serious trouble and make no advancement, begin to take on a new growth attended with pain, loss of weight and anemia they may be looked upon with great suspicion if the change occurs after the menopause. This fact suggests the danger which may arise in allowing these apparently harmless uterine tumors to remain, and whether the risk of letting them alone is not greater than the risk of life in their removal. There can be no question on this point, if after 50 years of age a more or less rapid growth is discovered, but then it may be too late for the best results. Is it not true that any form of uterine growth is a menace to life at some time, even if it is apparently stationary?

#### THE RELATIONSHIP OF ANTISTREPTOCOCCUS SERUM TO THE TREATMENT OF PUERPERAL SEPSIS.

GEORGE E. RANNEY, M.D.

Ex-President Michigan State Medical Society; President United States Pension Examining Board at Lansing; State Inspector of Communicable Diseases; Member of the Michigan State Board of Registration in Medicine, Etc.

LANSING, MICH.

Since the first disturbances of unknown origin in the puerperal state, up to the time of Semmelweis, who stimulated investigation of fever in the puerperal state, this subject has been the bone of contention and the *modus operandi* for its successful treatment has been the highest aim of all clinicians.

Serum therapy has been deemed ideal for the treatment of diseases due to specific organisms. Pasteur, Koch, Behring and others contended that the bodily

functions in the destruction of toxins could be increased by the introduction of the attenuated serum of those definite organisms. Theoretically this worked admirably, but thus far the only successes are in diphtheria and tetanus, and in the many experiments conducted with antistreptococcus serum we do not in all the literature find one report of its value in the prevention of infection from the streptococcus. In animal experimentation, J. Petruschy<sup>1</sup> says: "The protective power against infection with streptococcus Starmock, as well as two forms from Lyons, did not show any protective power against infection." He also states that serum can not be recommended for use upon man, and also that positive knowledge for a serum therapy against streptococcus infection has as yet not been produced.

Of course, I admit that there are some cases reported in the literature in which recovery has been stated to be due to this form of treatment. I here agree with Petruschy when he states that all other forms of treatment were indulged in, and why can not the recovery be attributed to other forms of treatment or to nature? In none of the cases that we have reviewed did we find the only treatment that of the serum.

Williams<sup>2</sup> reports fourteen cases of puerperal septicemia treated by antitoxin. In these no benefits followed the injections. Of the two fatal cases, in one the course of the disease was not affected by the serum; the other died during convalescence, the fever having run its course. The physician who performed the autopsy considered the death due to the serum.

We must note that the true founders of this form of treatment have also grown skeptical as to its absolute benefits. Another writer<sup>3</sup> states: "The reports of the English and French journals of cures as a result of serum treatment must be looked upon with suspicion."

This brings me to a case unsuccessfully treated by me and my medical counselors.

Mrs. —, aged 25, primipara. Spontaneous birth after six hours, the whole labor being uneventful, save for a superficial tear of fourchette. Temperature and pulse normal and general condition favorable. As is my habit, I directed the nurse to use vaginal douches of water and formaldehyde twice daily. Up to the fourth day everything seemed favorable, when the temperature suddenly rose to 102.5 without an initial chill. I then immediately examined her and found nothing to which I could attribute this sudden rise of temperature. I immediately ordered a purge and a freer use of the antiseptic douche. The following day, the temperature still remaining high, I gave her an intra-uterine douche of formaldehyde and water and repeated it the following day and informed the family that a consultant should be called in. Her uncle, being a prominent member of the profession, was sent for, but as he was not at home his confrère, Dr. —, came instead. About this time an exudate made its appearance on the abraded surface of the fourchette, and the nurse was directed to make frequent applications of peroxid of hydrogen to those parts. On careful inquiry I learned that the nurse employed by the patient had recently been attending a family with membranous tonsillitis and that she herself had but just recovered from the same disease. Characteristic of the "meddlesome women" she undertook to improve upon my treatment by applying large quantities of vaselin from an open jar on the abraded surface and into the vagina after each douche, without my knowledge, thus defeating largely the very object of the cleansing process. This fact, together with the knowledge of her recent experience with membranous tonsillitis, accounted, of course, for the source of sepsis in this case. On advice of Dr. —, vaginal and uterine antiseptic

douches were continued,<sup>4</sup> and the exudation continuing to extend up the vagina, clear to the fundus of the womb, Dr. Goodell's solution of hydrate of chloral, iodine and carbolic acid was applied to the parts involved twice a day for the purpose of destroying the membrane. Antistreptococcal serum, 10 c.c., twice a day, was injected for three or four days, producing some unpleasant local effect, the parts looking red, the integument raised and edematous, presenting a smooth shiny, pale-yellow surface, somewhat mottled with infiltration into cellular tissue. The temperature varied from slightly above normal to 104.5 and 105, without reference, as far as I could see, to the use of the serum. Either one or the other or both of the consultants saw her or were communicated with every day by telephone, and their efforts, as well as my own, were untiring, active and unremitting. Quinin and nuclein were given and laxatives as required.

Before the termination of this case Dr. —, in a paper read before the Michigan State Medical Society, May 5, 1899, said: "I saw her on the fifth day after confinement. Her temperature was 104 and had been nearly that for 48 hours. A thick white membrane covered the surface of the perineal laceration and other abrasions of the vaginal wall. . . . Nuclein solution and quinin were prescribed. The next morning the temperature was normal and remained so until toward evening the next day, when it began to rise, and increased steadily until noon of the eighth day, when it registered 103."

The wide variation of temperature at short intervals characteristic of this disease was a marked feature in this case, from its beginning to its termination, ten weeks later, and these exacerbations of fever were not preceded by chills and fluctuation of temperature did not seem to bear any relation to the medication employed.

The temperature had varied from 101 to 104 during 48 hours. There were no vaginal abrasions or exudations except at the fourchette, but despite all treatment the exudation extended gradually up from day to day, involving the entire vaginal wall and cervix, till it reached, about the third week, the end of the uterine canal.

A marked feature in the case was a high temperature every seventh day from the first to the tenth week, when she died. At the first visit of Dr. —, beside the treatment above mentioned, the nurse was directed to apply the peroxid of hydrogen, and he recommended Goodell's iodine, carbolic acid and chloral mixture to be applied if the exudation continued. Dr. — visited her again the third day following his first visit and her symptoms not having improved and the exudation continuing, he applied the Goodell mixture to the abraded surface and injected the same into the uterine canal, and the vagina was packed with iodoform gauze and vaginal and uterine douches continued till about the thirteenth day, when the membrane ceased to form.

The diagnosis of streptococcal infection had been made and the antistreptococcal serum was used hypodermatically once in twelve hours, till three doses were given and after a short interval six more were given, making nine in all. Inasmuch as the nurse in attendance had just returned from a case of membranous tonsillitis it can not be denied that the infection may have been diphtheritic rather than simply streptococcal. We could scarcely suppose that so thick a false membrane could result from a simple streptococcal infection. It would rather suggest wound-diphtheria and would therefore require antidiphtheritic serum.

Though never having used the serum, I had but little faith in its virtues, but was encouraged in its use in this case by the consultant, who, in writing of it in connection with this case, says: "If we find that patients so virulently infected as this one was recover under its use, while others under usual forms of treatment, without its use, almost all die, there must be virtue in it. In some cases it works as positively as does the antidiphtheritic serum." She is in excellent spirits, has no

4. The continuation of the uterine douches was repeated only on his advice, as, owing to conditions unnecessary to explain in this connection, all treatment recommended by him and his associate consultant was carried out.

5. This was written before the patient died.

pain, excepting after examination, has had no symptoms of systemic infection, having had no chill or sweating. Her temperature for the past three days has ranged lower, showing minimum of 98.5 F. and a maximum of 102.5." Mace<sup>6</sup> states that serotherapy has proved a failure and is rapidly being abandoned and that the Institut Pasteur itself has admitted the action of the Marmorek serum unsatisfactory.

The patient's appetite and strength and circulation kept good, and she looked cheerful, and neither she nor her friends could feel that she was very ill during the first few weeks of her malady. There occurred, early in the case from inflammatory action, a thickening of the left broad ligament and enlargement (though not marked) of the womb. Later the right broad ligament became involved, but its enlargement soon disappeared, under the persistent and thorough use of hot vaginal douches. The nineteenth day from the inception of the fever, the consultants thought they discovered evidences of pus in the left broad ligament, which I was frank to say I doubted.<sup>7</sup> Operation for the removal of pus was postponed for five days, when she was placed under ether and chloroform was given, and two or three attempts were made with a trocar to reach pus in the broad ligament through the vagina. This thorough exploration revealed no pus, and 26 days from this examination the patient was placed under the influence of chloroform and an abdominal section made. No pus was found, but of course the plastic inflammation of and about the broad ligament involved the Fallopian tube. The tube, slightly enlarged, was removed, but when laid open no pus was found. In a case so serious as that of streptococcal infection in the puerpera, no mind is so gifted as to see the end from the beginning, but it seems to me that it would require no superhuman gift to anticipate the result in this case. Fifteen days following this the patient died. A few days following the etherization and exploration with trocar for pus, on examination of the patient's urine I found it contained considerable mucus, blood and pus and other evidences of a well-developed case of acute nephritis, edema of her limbs, hands and face and different parts of the body changing, more or less, from place to place, being more marked in pendent portions, the lungs becoming somewhat involved and pleuritic effusion being present.

A drainage tube was left in the surgical wound of the abdomen and about three ounces of serum were removed through it twice a day until a day or two of her death, when, coming away spontaneously, it was not replaced. After the diagnosis of nephritis saline cathartics and digitalis were freely used. She died in a spasm from uremic poisoning.

We are prone to report our successes and especially if we can attribute them to means or fads not in general use by the profession, but it is no less our duty to record our failures as a warning to others.

Left to myself to treat another case like the one above described, I would not employ: 1. Antistreptococcal serum. 2. I would not administer ether. 3. I would not explore with trocar for pus. 4. I would not cauterize abraded surfaces to destroy exudation. 5. I would not make an abdominal incision during the course of the septic fever, unless the pus accumulation had become localized and demonstrated. 6. I would not make it then till after leucocytosis had been determined. 7. I would not subject the patient to the shock of any operation until the pus had formed and become localized and could be easily removed without severe shock to the system.

The fact that no pus was formed is not, in my opinion, due to the use of the serum, but to the frequent and persistent vaginal douches, eight gallons at a time, much of the time once in three hours, the douches being grateful and restful to the patient.

6. *Obstetrics*, June, 1899.

7. Patient had no chill, no severe pain in region of tubes, no reflex symptoms, vomiting, etc., no rectal or vesical irritation, no abdominal symptoms. Her appetite was good and she slept well. For those and other reasons I believed no pus had formed, the case being exceptional in that regard.

We all know how the kidneys are susceptible to disturbances during and following pregnancy, and especially must we note the deleterious effects of ether upon the kidney, so much so that many surgeons, especially in Europe, discard its use almost wholly as an anesthetic. So in case of an acute attack of nephritis following its use in such a depleted condition, can we not conclude, after knowing that a patient had during the whole period of pregnancy shown no disturbances in this direction, that the ether was the cause?

Hence, in such cases, where the patient is thus depleted, should we not hesitate, in view of the inhalation of ether having such a strong tendency to produce an acute congestion of the kidneys, especially as this form of congestion is almost always fatal? I would not have administered an anesthetic without first ascertaining, by an examination of the blood, if pus were present—the blood, if pus was present in the system, would show a marked leucocytosis, both absolutely and relatively, there being particularly a great increase in the polymorphonuclear leucocytes. There are two exceptions to this rule. Leucocytosis might not occur first where a pus cavity is walled off by adhesions, and second, in cases where the system was overwhelmed by the poison, for in these cases a negative chemiotases seems to be present, neither of which conditions would apply in this case, for the presence of pus during the active stage of the disease would be less dangerous than the danger of an almost certain septic infection of the peritoneal cavity, by an attempt at its removal by abdominal incision.

Besides the high blood pressure produced by the inhalation of ether being directly injurious to the kidneys, do we not in such a case of septicemia have special reasons for withholding it, in view of the well-known fact of such extensive destruction of the blood corpuscles in septicemia leading to a weakened condition of the walls of the small vessels, in many cases to extensive hemorrhages, both with the subcutaneous and submucous tissues; why then not into the kidney, producing in this way acute nephritis?

I would not, during the active stage of the disease, explore with trocar the broad ligament through the Douglas cul-de-sac for pus. I would not cauterize abraded surfaces to destroy the exudate, a product, not a cause of the disease. What physician of the present day cauterizes diphtheritic membrane to cure diphtheria?

I would not, during the progress of the fever, subject such a patient to the additional shock of an abdominal incision or any operation. Certainly I would not operate until the presence of pus was proven by blood test, if necessary, or the pus pointed and could be easily reached without shock to the system.

This brings me to the brief consideration of some cases that I have seen as a consultant and what seems to me to be the most rational treatment of them.

CASE 1—I saw her Jan. 2, 1901. Age 21; occupation, housewife. Menstruated first when 16 years of age, regular every four weeks; last was ten months ago, duration 4 days—delivered by midwife, child six days old, character of labor was normal. This was her first child and she never had any abortions. Condition of patient when I first saw her: Duration of disease was four days. She had pain in the lower part of the abdomen and had a reddish discharge. Micturitions take place frequently, about every three hours. Upon examination large broken-down exudative patches were visible on the anterior and posterior vaginal walls and apparently extending into the cervical canal. A sound was passed for the purpose of diagnosis and a vaginal douche of bichlorid, 1 to 5000, was given.

Patient's temperature on my first visit was 106, pulse 140, respirations 24. This temperature fluctuated, the first day from 106 to 102, then to 105 and back again to 102; second day, temperature was 106, pulse 130, respiration 48; third day, temperature was 100, pulse 112, respirations 32; fourth day, temperature was 104, pulse 116, respirations 34; fifth day, temperature was 98, pulse 104, respirations 30. There was a daily fluctuation ranging from 103.4 to 99.8 for ten days following, when on the sixteenth day the temperature rose to 105 and fell the following morning to 100. This fluctuation kept on gradually decreasing until on the 22d day, when the patient's temperature reached normal part of the day and did not go above 101. At my first visit quite a large mass was diagnosed, involving left broad ligament, and three days later blood test showed marked leucocytosis, but no attempt was made at that time to explore for pus. Urine examination was negative. Pathologic examination showed streptococcal infection. General treatment was sponging with alcohol and water when the temperature rose above 103. Milk diet and beef juice; whisky was given every three hours. Strychnin sulphate gr. 1/60 once in three hours. Bichlorid douches 1 to 5000 twice daily. Bowels kept regular by laxative salines, enemas and occasionally calomel. At the end of six weeks from my first visit her temperature was but slightly above normal, and what fever she had I attributed to other causes than streptococcal poisoning. Fluctuation could be felt from the Douglas cul-de-sac to the posterior lateral aspect of the uterus on the left side. The pus having pointed I emptied the abscess by incision at this point, causing but little pain and no perceptible shock, from which time the patient progressed to a satisfactory recovery.

CASE 2.—I saw her Jan. 12, 1901. Age 20; married four years; occupation, housewife; menstruated first at 15 years of age; regular in character, period of four weeks; last was in the middle of September, lasted three or four days. Patient gives history that some time in last September she was cured. Present illness dates from a few days following curettage, made because she was barren, and to overcome sterility.

January 12, patient's temperature was 97, pulse 160, respirations 32; on the same day temperature rose to 103.4. From 17th to 23d it fluctuated from 99.4 to 103.

The patient looked blanched, and blood examination showed marked leucocytosis. On examination of her vagina quite an enlargement was found posterior and to the right of the uterus, involving the broad ligament. The tumor was hard and I could detect no fluctuation. She was too feeble to undergo any operation had one been desirable. Treatment in general was the same as that employed in Case 1, except that bichlorid was not used in douches. From this time on temperature fluctuated from normal to 103, till on April 8 the fever had entirely gone. At this time fluctuation being found just to left and posterior to cervix I removed the pus by a free incision and the patient went on to a satisfactory recovery.

I report the last two cases mentioned above to show the treatment, which not only in these cases, but in quite a number of others in my experience, most satisfactory recoveries followed, though the disease was somewhat protracted, which is usual in such cases. The profession being ever ready and anxious to conquer disease, there is constantly being evolved, through the application of intellectual experiment and money, new remedies to accomplish this end. Diphtheria, over which science has achieved such glorious victories, is an example of a disease which has been arrested and humiliated by the application of attested scientific methods. But the admitted virtues of anti-diphtheritic serum may, and I think has, stimulated the over-credulous and enthusiastic to use a variety of serums of more than doubtful utility, if not absolutely harmful, as was demonstrated in the use of the Koch lymph for the cure of tubercle, and I think I may say in the use of the serum in puerperal streptococcal poisoning in the puerperium.

## SURGERY OF THE LIVER.

CARL BECK, M.D.

CHICAGO.

It is only within recent years that the liver has received the attention of surgeons. Operations upon this organ were dreaded on account of the profuse, at times uncontrollable, hemorrhage which followed the cutting into the very vascular organ. This was observed in cases of injury of the liver, where the surgeon often was helpless in trying to check the bleeding by methods which would be applied in other organs.

Another reason why surgeons hesitated to remove large portions of the liver was the uncertainty of the physiological after-effects in the destruction of a large part of the liver substance. The knowledge on this subject was very imperfect, and when a surgeon was confronted with a case requiring resection of a large portion of the liver, the picture of acute yellow atrophy and its fatal results stood before him and naturally he was not very enthusiastic.

Spontaneous healing following injuries resulting from accidents of the liver substance first suggested to the surgeons how to deal or attempt to deal with such wounds.

In 1870 Bruns treated a gunshot wound of the liver by resection of the lacerated portion, and the patient recovered. In 1886 Linz removed a solid tumor of the liver, and though the patient died the feasibility of an operation on the liver substance was proven. Since that time, a number of operations on the liver substance have been reported, the majority being with fairly good results. In studying the details of these reported cases, we note that they were not well-planned operations, but inventions of the moment, because the conditions requiring the operations were discovered accidentally after opening the abdomen, either after a wrong diagnosis or a probatory incision in doubtful diagnosis.

There having been no definite technique or rules in the removal of tumors from the liver, we can readily understand that the methods were quite primitive, such as removal of the growth by a finger-nail or a spoon.

A step forward was taken by the very interesting and important experiments on animals by Gluck, Tizzoni, Griffini, Podysotski, and especially by Ponfick and Kahn. They have all proven that on animals a resection of a considerable portion of the liver is possible and compatible with life and that the damage is soon repaired. Ponfick, for instance, was able to remove two-thirds of the liver without causing the death of the animal. These experiments and very favorable results encouraged surgeons to work on the human liver. All that was then needed was a perfect method of controlling the treacherous hemorrhage of the liver and the two objections mentioned would be overcome. Work in this direction was carried on with equal zeal, of which the publication of Kausnetzoff and Penski, and of Auvsay and Terrier, published in the "Revue de Chirurgie," 1896 and 1897, are the most important ones. Other individual observations and operations by reliable surgeons were reported.

The methods so far advocated by different authors may be summed up as follows:

1. Removing the liver tissue by cauterization alone.—Jacobs.
2. Cutting away the pathologically changed tissue following the cut with the thermo-cautery.—Bruns.

3. Curetting and tamponnading afterwards.—Mikulicz and Schmidt.

4. Cauterization and ligature of some vessels which continued bleeding after cauterization.—von Eiselsberg. Tuffier found this method reliable, as the vessels can withstand a good deal of stretching. Keen operated on a case by this method with good success.

5. Ligature *en masse* with elastic material before removing the tumor.—Lucke and Israel. A modification of this method is to leave the elastic ligature until the danger of secondary hemorrhage has passed, and securing the stump, preventing the slipping back by long needles, a method well known formerly in the extraperitoneal treatment of fibroids.—Sklifassovski, Rosenblatt, Bastianelli.

The Suegiereff method, i. e., the use of hot air or steam as a hemostatic, has been abandoned, for the reason that it was not possible to apply it to small areas. It produced a cooking effect on the surrounding structures, even if they were well protected.

Kausnetzoff and Penski have made a great many experiments on animals, from which they deduct the following conclusions:

1. Lightly drawn ligatures are of no value.
2. The intraperitoneal treatment of the stump after resection is preferable to the extraperitoneal.
3. Blunt needles do less harm in sewing the liver than sharp needles.
4. Gradual tightening with elastic material is thoroughly hemostatic.
5. The vessels resist a good deal of weight and pressure, and ought to be tied individually.
6. The omentum should not be used to cover the liver stump, as it does not increase the hemostatic effect.
7. A transverse incision to reach the liver is preferable to any other.

Keen and others have collected and tabulated the cases in detail, and given their own experiences. Remarkably good results were obtained in most of the cases, but from the perusal of the descriptions it was evident that there was still no reliable method of dealing with one of the greatest dangers of these operations, i. e., the hemorrhage. Even if Dr. G. V. Segale, of Genoa, considers the problem solved by the ingenious method he has devised, it seems that such is not the case. More experiments and observations will be necessary before we have reached a faultless method.

My attention was called to this subject by a case which occurred in my practice in 1892. A boy, about 10 years of age, accidentally shot himself with a toy gun, 22-caliber. In trying to hide the weapon underneath his vest, he accidentally pulled the trigger and the bullet was discharged, entering his right epigastrium below the costal arch. The bullet took a downward course, penetrating the liver, perforating a few loops of the intestine, finally entering the bladder, and by contractions of this organ the bullet was passed halfway down into the urethra, blocked the same, causing stranguria. I saw the case a few hours after the accident. The fact that the boy had been shot had not been known to the physicians or the parents up to that time; their attention was directed to relieving the stranguria and collapse.

Upon opening the abdominal cavity, we found it filled with fresh blood and coagula. The first injury discovered was the lacerated border of the liver, which still bled freely. A compress was tightly kept over it by an assistant, which temporarily stopped the hemor-

rhage, while we proceeded with the examination. When the intestine and the bladder had been sutured, the compress was removed from the liver, and we found that the hemorrhage had nearly stopped. I was inclined to resect the ugly torn substance, being afraid of infection from it, but I refrained from so doing for fear that a new hemorrhage would be started by a fresh cut, and perhaps be fatal to this already very anemic boy.

Further experiments on animals convinced me that the liver substance removed in small pieces from the border of the liver may safely be sutured without causing the death of the animal. Subsequently during my Cook County Hospital service I was able to verify this, especially in the case of a stab wound through the liver. In this case I put several sutures into the liver substance, and obtained a good result. I desire to report another case, that of a young woman, who came under my observation in 1894, in whom a diagnosis of inoperable cancer of the stomach with metastatic tumors of the liver was made by a leading surgeon, and operation refused. The diagnosis seemed to me doubtful, and I made an exploration. I found a tumor the size of my fist at the anterior border of the liver, yellow in color, glistening and surrounded by a somewhat congested area. The stomach and intestines were not involved. I was very much tempted to remove it, on account of its favorable location, but the first small incision made into it caused me to stop, on account of the profuse hemorrhage; I hastily closed it with a few sutures. I was afterwards glad I had not removed the tumor, because while manipulating the liver I discovered that there were smaller lumps on the upper and posterior surface of the same, and I suspected that I had to deal with a case of "Multiple gummata" of the liver. My suspicion was verified by a rapid disappearance of the tumors by vigorous antisyphilitic treatment.

In 1896 I again had occasion to observe a tumor of the liver which seemed to be a promising case for resection, but having had no definite method of technique, I refrained from operating. I then began to experiment on animals, with the object of devising a method which would promise a good result in this case.

Where lay the fault with the methods already in vogue? What particular danger was to be feared in the operation in question? First of all, I concluded that the wound should not be drained. Drainage introduces many dangers. For this reason it was essential that absorbable suture material should be used. Second, the hemostasis should begin even before the cut is made into the liver substance. If we begin to enucleate a tumor and try to ligate or pack as we go on, the hemostasis will be only partially checked. If we apply the cautery, we darken the tissues and can not distinguish pathologic from normal tissue, because when burned they both look alike, and we are liable to leave some of the pathologic tissue behind.

Catgut or silk without any support cuts through the liver structure with great ease, and therefore is not practical. This was proven by many investigators who had worked on this problem before I did.

It was therefore necessary to find some material for the support of the ligatures. The most suitable for this purpose seemed to me to be decalcified bone recommended by Professor Senn for similar purposes. We began to use the same in oblong pieces, perforated at either end with a small punch, passed the catgut through these holes, and tied them in the manner of a quilt suture. The method was identically the same as

that described by Dr. Segale, with the exception that he used ebony or ivory rods or tubes. These are not absorbable, or only partly so. His method is the following: He uses small beads of ebony or ivory, which are hollow, and fit one into the other at the ends, and are threaded with catgut so as to form a small flexible rod. The material was chosen because it lends itself to disinfection, and the bead-like arrangement favors encapsulation of each bead. The technique of the operation is as follows: At the boundary of the lobe of the liver, which is intended to be removed, and along the transverse line there are passed several such loops of rods, so as to compress a triangular piece, the base of which is directly towards the operator. The string is tightly drawn and knotted, and then the tissue resected. The secondary hemorrhage is thus avoided, and intraperitoneal treatment of the stump possible. The catgut is absorbed, the rods break up into their small components, which are then encapsulated by connective tissue. Segale believes to have solved the problem by this method.

With the difference of the material—his being ebony or ivory beads, ours decalcified bone plates—the methods used in our experiments were nearly the same, but in my cases I found on postmortem on the animals local abscesses around the partially broken-up decalcified bone. These were firmly surrounded by adhesions to the stomach and intestine. This, of course, was undesirable, although such abscesses and even the unabsorbed suture material usually break into the intestine and heal out; still there were dangers in this method of healing; for, strictures, ulcers and other unfavorable sequelæ might result, and consequently I advised the use of absorbable material in the abdominal cavity. If, for some reason, silk had to be used, it should be used in interrupted sutures, so as to make the eliminative process easier.

I was about to abandon my experiments, when upon the suggestion of my brother, Dr. Joseph C. Beek, to utilize living tissue from the abdomen of the animal for the support of the sutures, I renewed them. The method was carried out as follows: From each border of the incision into the abdomen we slit up a broad band, including the peritoneum, the fascia, and in some cases also the muscle. This strip was left attached at one end to the abdominal wall. These strips were used as supporters for the suture material by encircling the liver with them where the sutures were intended to be placed, and the catgut sutures were passed through these strips and tightly drawn, in the same method with which the decalcified bone plates were used. The results were most gratifying and at a November meeting of the Chicago Medical Society, in 1898, I exhibited some specimens of these experiments.

After November, 1898, I discontinued the experiments on the liver, and have had no opportunity to give the subject my attention, until of late, when a case occurred in my practice which proved to me that after all we had not yet solved the problem of resection of large portions of the liver. This case is in many respects unique, and illustrates many points of pathology and technique in the operation. The following is a detailed report of this case:

F. K., 20 years old, porter, remembers having had a prolonged fever when he was a very young boy; the nature of this he has never ascertained. At the age of 6 he had mumps. At 18 he suffered from gonorrhea, made a quick recovery, but never had a syphilitic infection.

About five years ago the present illness began. He received a severe kick in the abdomen in an altercation with a companion. The pain was so severe that he had to go to bed and remain there several days. The pain was localized in the left upper part of his abdomen for several weeks, disappeared for a time, but returned as soon as he resumed work or lifted anything heavy. At such times there appeared a swelling in what he called "a weak spot," which subsided after application of turpentine and reappeared again. After several such experiences he noticed a gradually growing tumor in the left upper abdomen, which caused shortness of breath, especially in lying down. A cough with expectoration of thick mucus set in and annoyed him greatly. Of late he had been feeling miserable, declined in weight; his temperature varied, sometimes below, sometimes above normal. He lost his appetite and his bowels were very irregular. When offered an operative interference a few weeks ago, he declined, but now he begs for relief, even at the risk of life.

Status on Admission: Tall, thin, colored man, with normal conditions of head and face, slight bronchitis of both lungs, normal conditions otherwise of lung and heart. While standing we noticed a bulging beginning at the lower anterior chest wall of the left side at the height of about the 6th rib, becoming more and more prominent in the epigastrium, being pear-shaped in contour. In the recumbent position the mass which forms this prominence becomes more visible in the epigastrium. A moderately marked resistant, globular hardness are the characteristics of this tumor, which does not show fluctuation on any part. It is slightly movable from above downward, but seems to extend under the arch of the ribs and also slightly movable from side to side, though not to a great extent. The percussion shows that the hepatic dullness passes directly into this tumor; that the hepatic dullness on the right side does not extend as far below as normally; that the tumor extends about two inches below the umbilicus; on the back the dullness begins in the 6th intercostal space and reaches down as far as the line of the third lumbar. Otherwise the abdomen seems normal.

The patient has a temperature of 101.6, pulse 96. He coughs considerably and expectorates a yellowish, tenacious sputum. He is highly dyspneic. There is pain but no tenderness. Urine shows trace of albumin; otherwise normal.

Diagnosis: A tumor of the omentum, tumor of the stomach, tumor of the pancreas, or of the left kidney, tumor of the spleen, were the possibilities. I did not think of the tumor of the liver because no symptom pointed to this organ. The greatest probability seemed to be a pancreas or omental growth.

Operation: Anesthetic was quite difficult on account of the bronchitis and dyspnea. An incision was made over the highest prominence, in a line parallel to the median, of about six inches. After exposing the growth it was found that the same was a tumor of the liver. The spleen was small; the left kidney normal and in normal place; pancreas normal, but the stomach was very much out of its normal place, being grown into the tumor so that it appeared half buried with a small curvature in the lower surface of the growth. The first act of operation consisted in the freeing of the stomach from its position. This procedure was slow and very tedious, the adhesions being firm and bleeding. Finally, I succeeded in separating the stomach, but not without having denuded its upper wall of a portion of peritoneum and muscle. The defect was sutured, whereupon the tumor became free. An examination of the tumor showed that it was of the size of a man's head, more or less pear-shaped, passing with its narrower portion into the normal liver tissue at about the gall-bladder, or slightly beyond. The normal right lobe was so small and flabby that at first I thought of a situs inversus, which idea, however, was disproven by the spleen being in normal position. The tumor was brought outward from the abdominal cavity down to normal liver tissue. For this purpose the gall-bladder had to be slightly separated, which caused a slight bleeding. Being positive that all the pathologic tissue was outside of the abdominal cavity, I proceeded to exclude by elastic ligature. This method was the only one available for this kind of tumor. We were not prepared to find this tumor, and had not planned

a method of procedure. Consequently, most of the apparatus for exclusion and separation of the tumor had to be improvised. At first a broad band of iodoform gauze folded four times was placed around the stump, which was then tightly constricted by a rubber catheter, No. 14, Nélaton, and held by an artery forceps. A second band of iodoform gauze with another constricting Nélaton catheter was applied about half an inch above the first, and in order to prevent the stump from slipping into the abdominal cavity, two hatpins furnished by one of the nurses improvised the apparatus necessary to prevent the retraction of the stump. Then the abdominal portion of the liver was carefully surrounded with draining gauze and closed as far as possible to prevent prolapse of bowel or other abdominal contents. The tumor beyond the second constricting band was then resected, leaving just enough tissue to make it impossible for this band to slip off. There was absolutely no hemorrhage from the stump after the resection, proving that the constricting bands were tight enough. This completed the operation. Figure 1.

Post-Operative Notes: The operation had lasted 1 hour and 20 minutes. The patient returned in good condition. There was slight irregularity of pulse, but no considerable shock. He

Fig. 1.—Shows the relation of tumor (4), stomach (5), and gall-bladder (6), the size of tumor about 2/3 of liver, two elastic ligatures (1 and 2), over gauze bands (3), leaving the gall-bladder within the healthy side; 7, small right liver lobe.

received a little cracked ice by mouth, but was fed entirely by rectum. Bowels moved slightly every day through the enemata. Temperature was from 101 to 102 continuously; the pulse 138 to 140. There was some oozing from the abdominal cavity during the first day, but on the third day, when the original dressing was removed, the hemorrhage had entirely stopped. A considerable odor from the gangrenous stump and a profuse malodorous discharge made it necessary to apply a considerable amount of orthoform. On the fifth day one of the rubber constrictors was removed. On the eighth day the second constrictor was removed, also the transfixing pins and a large part of the gangrenous stump was snipped off. About this time a considerable discharge of bile set in, apparently from large ducts, which were laid open near the line of demarcation. Firm adhesions of the healthy stump to the abdominal wall had formed by this time. The symptom, however, a high temperature, at times as high as 104, remained unexplained, inasmuch as there was no symptom of intra-abdominal inflammatory condition. Inasmuch as the patient had a cough and expectoration, we were inclined to think of tuberculosis, but the repeated examination proved it to be negative. Finally the fever went down, and on the 16th day the patient was

allowed to sit up in bed. On the 27th day he was moved into a chair; on the 34th day he was allowed to walk around. At this time the abdominal stump of sloughing liver had almost dwindled down to the size of a walnut and was surrounded by healthy granulations.—Fig 2.

Twenty days after the operation a suppuration from the right ear set in, which explained to us partly the fever of the patient. Several weeks after the operation the patient was able to go before the Chicago Medical Society to be demonstrated. At this time the abdominal wound was almost closed. The examination of his liver showed that the right lobe gave about twice as large an area of dullness as before the operation, indicating that a restoration of liver had taken place. For some time after, the patient gained, but about the middle, or toward the latter part of November, he had a recurrence of fever, pain in the ear, and some cough again. Inasmuch as his liver was entirely healed up, I inclined to the belief that this temperature was due to tuberculosis of his middle ear, and in order to give him the benefit of a better climate, he went to the South. I receive

Fig. 2.—Thirty-four days after operation.

a letter every week informing me as to his condition, which thus far is improving.

The specimen was immediately brought to the laboratory of Professor Zeit, who was inclined to pronounce it, from the macroscopic examination, an angioma. Microscopic specimens were prepared and showed, besides the large blood-filled cavities, which make up the bulk of the tumor, small areas of positively new-formed tissue of glandular character; so that we thought we had to deal with a tumor of angio-adenomatous character. Dr. Max. Herzog kindly examined some of the slides and believes the tumor to be an angioma. Microscopically it appears to be composed of large cavities filled with coagulated blood between small islands of liver tissue and connective tissue. The size of the tumor was that of a child's head and one could say it amounted to about two-thirds of the whole liver—Fig. 3.

The reason why I did not in this case employ the method which proved so successful in my experiments on dogs was that there was too much temptation to treat this tumor extraperitoneally. The tumor was so large that I could make it pediculated, but the patient was

exposed to great danger of infection. There was sufficient opportunity for it. A vast gangrenous surface, resorption of foul material for weeks, drainage of bile and danger to the life of the patient—all these could have been avoided had we used the intraperitoneal method. It was by mere accident that the patient escaped these dangers.

This case again prompted me to conduct more experiments on animals, which I desire to report in this paper.

No. 1.—A medium-sized dog was chloroformed and through a longitudinal incision in the region of the gall-bladder a lobe of the liver was brought out. Several sutures of silk were inserted, starting with the fascia, then the peritoneum, then through the liver and again in the opposite side through the peritoneum and fascia. In this way the liver was practically clamped between the two abdominal walls. The protruding portion of the liver was then amputated. The constriction of

Fig. 3.—Slices of tumor proper, showing cavities with coagulated blood.

the silk ligatures, which had been previously tightened, prevented bleeding from the cut surface completely. In order to prevent retraction of the stump, before firm adhesions would be produced, all tissues including the skin on both sides were transfixed by two long pins crossing each other. The superficial fascia and the skin were then separately sutured over the stump. This dog unfortunately died from peritonitis forty-eight hours after operation. On postmortem examination there were no signs of hemorrhage, but no adhesion had taken place, probably on account of the infection of the peritoneum. To demonstrate the method of this operation, I have prepared a schematic drawing, No. 4.

No. 2.—A large-sized animal was chloroformed and an operation in every respect corresponding to the one of No. 1 was performed Nov. 4, 1901, by Dr. Hecht. The dog recovered, and two months later, Jan. 9, 1902, a second operation was performed by myself. A transverse incision along the border

of the lowest rib was made. The old sear contained a stump of the liver. The stump was completely surrounded by an adhesion of omentum, as though it had been soldered to the abdominal wall, but no intestines were adherent. The transverse incision permitted lifting out of the abdominal cavity nearly one-third of the remaining portion of the liver. A strip of gauze was placed around it, and slowly constricted, but nevertheless it cut through the substance of the liver on one side, and resulted in a slight oozing, which I thought would stop without any suturing. The abdomen was closed, as in the previous two cases, but the dog died the following day from the effects of hemorrhage, which was the result of oozing from the constricted portion.

No. 3.—Operation was same as in No. 1. The animal died from the effects of sepsis, but there was no evidence of any hemorrhage after the operation.

No. 4.—A medium-sized animal was chloroformed, and an attempt was made to remove the two lobes in a manner similar to No. 1. In pulling the liver upwards, however, a rent was produced in the central portion of the organ where the lobes originate. This was sutured by catgut sutures, with apparently a satisfactory result. The abdomen was then closed in the usual manner. The animal died the same day from the effects of hemorrhage from the rent in the posterior part of the liver. No signs, however, of hemorrhage were present in the stump, which was sewed into the abdominal wall.

No. 5.—Medium-sized female dog was chloroformed, and an operation in every respect like No. 1 was performed. No infection took place in this case, and the dog recovered and lived several weeks. On postmortem there were no evidences

Fig. 4.—1, skin; 2, S. fascia; 3, muscle; 4, suture of liver fascia and peritoneum; 5, peritoneum; 6, deep fascia.

of hemorrhage; simply the adhesions of omentum around the portion which entered the abdominal wall.

No. 6.—An operation in every way like No. 1 was performed, with apparently complete hemostasis. Before closing the abdomen, however, I decided to make another resection deeper down, with the preliminary compression of a gauze bandage, as I had done in the case No. 2. In doing this the liver substance was again torn by compression with the gauze, and bled freely, leaving an irregular, lacerated wound of the liver running backwards. The flaps were not long enough to encircle the posterior part of the liver, and it was impossible to stop the hemorrhage, and the animal died from the effects of hemorrhage the same day.

No. 7.—In this animal the same experiment was made as in No. 6. In this case, however, large and broad flaps were secured. No difficulty was encountered hereby. The right part of the liver was almost entirely removed, and controlled with the compression and suture, which was supported by the flaps. This dog recovered, and was killed three weeks later, showing that the hemorrhage can be prevented by the method pursued in these experiments.

The lesson taught by these experiments is that it requires broad and long flaps of fascia and peritoneum in cases where a large portion of the liver is to be removed, using the gradual slow constriction of the organ before placing the sutures. From my observations on

the cases of the human, and experiments on animals, I would draw the following conclusions:

1. Liver tissue of considerable size may be safely removed by previous anemization of the part which is intended to be removed.

2. That for the support of the ligatures living tissue from the same animal, preferably the fascia and peritoneum from the abdominal wall, is best suited.

3. That the intraperitoneal or the intraparietal method is preferable to the external method.

### A CASE OF INFANTILE CEREBRAL PALSY, WITH AUTOPSY FINDINGS.

L. PIERCE CLARK, M.D.

AND

T. P. PROUT, M.D.

NEW YORK CITY.

The lesions found at autopsy in old infantile palsy cases are variable. The findings are for the most part porencephaly (more frequently pseudo-porencephaly, often mistaken for porencephaly), small and indurated convolutions, single or multilocular cysts and microgyria. There may be but little or no evidence of the initial cerebral lesion. In the great majority of cases, however, there is usually some non-development of the cerebral convolutions in which the whole hemisphere of the side involved often unequally participates.

Fig. 1.—Cerebral hemispheres immediately after removal from the skull. The frontal lobes are located anteriorly. The left hemisphere is seen to be much smaller than the right. *a*, porencephalic areas in left hemisphere still filled with fluid. *b*, "Bear claw" bony formation in dura mater. *c*, Depression between right ascending frontal and middle frontal convolutions. *e*, Similar depression and break in right ascending parietal convolution. *f*, Fold of the dura mater. *d*, Border of the larger (left) hemisphere of the cerebellum.

The cerebellum of the same side or of the opposite side may also enter into the atrophy or non-development. The cerebellar lesion occurs on the same side if the pressure of the early lesion (hemorrhage) was great, or on the opposite side if the lesion resulted in large surface destruction or secondary atrophy of the hemisphere. There are, however, many varied changes present in individual cases; for instance, the calvarium and fossæ may be involved in the lesion. There may be low-grade formative connective tissue cysts, calcareous plaques, internal or external hydrocephalus, in which latter condition the degree of cerebral atrophy is secondary. The degree and extent of the unilateral lesion is often shown in motor and special sense defects. However, very frequently the clinical symptoms fail to give an adequate idea of the site and extent of the lesion. This is due to the fact that the symptoms which follow injuries in the

silent regions are unknown, as is also the degree of compensation possible in the unaffected areas in the same hemisphere and the extent of bilateral representation of cerebral processes in the cortex.

An interesting case of infantile cerebral palsy in which epileptiform crises developed and in which multiple lesions were found to exist at autopsy is as follows: M. E. C., aged 29, unmarried, was born at term; labor normal. There was no disease in infancy until the onset of infantile cerebral palsy at 2 years of age. The palsy was supposed to be caused by fright. It was attended by "fever, convulsions and great prostration for several days." The whole right side was paralyzed. In the course of several years she regained considerable use of the leg, notwithstanding the occurrence of marked atrophy and maldevelopment of the muscles and bones of the right arm. The arm was entirely useless and developed the usual condition of spastic rigidity. Lack of development was marked and the extremity always remained infantile in appearance as shown in Fig. 7. At the age of 6, epileptiform crises appeared. They began in the right face and shoulder muscles. For the first seven years the crises were confined to that side without loss of consciousness. At 13 the attacks became typical grand mal, with right-side order of invasion, and an epigastric aura. For the past two years, two or three attacks occurred daily. The patient was feeble-minded although able to read and write and do ordinary housework. Old cicatrices were present on both cornea and chronic conjunctivitis was present, yet the corneal scars were not central and interfered but slightly with vision.

Fig. 2.—The small left cerebral hemisphere is shown against the larger right cerebral hemisphere. The small atrophied convolutions of the left hemisphere are shown with porencephalic areas collapsed. *a*, Porencephalic areas in parietal region. *b*, Porencephalic area in temporal region. *c*, Large left hemisphere of cerebellum; the relative size of it and the left cerebral hemisphere is apparent.

Ophthalmoscopic examination was negative. There was bilateral paralysis of the levator palpebræ with marked ptosis on the right side. All the deep reflexes were greatly exaggerated in the paretic parts. Several periods of serial attacks occurred during the past year. A series of attacks which occurred April 5, 1901, was very exhausting and temporary loss of speech followed each attack. When free from seizures the speech was normal but slow and drawling as commonly found in the mentally deficient. All seizures began and ended on the right side (face and shoulder), the head was always turned to the right. Occasionally, after the right side contractions ceased and the convulsion had apparently ended, the left arm and leg showed a series of three or four sharp clonic contractions.

On July 4, 1901, the patient passed into a condition of stupor and delirium constituting the status equivalent. The cardinal curves of this fatal coma are shown

in the graphic chart. Patient died of the status equivalent on July 9.

#### PATHOLOGIC ANATOMY OF THE CASE.

The autopsy was necessarily postponed until 30 hours after death. The body was well nourished; rigor mortis was marked. There was no asymmetry of skull or face. The right upper extremity was small, ill-developed and presented marked contractures. Although the right lower extremity was poorly developed, atrophy and contractures were not so marked as in the right arm. All the muscles of the right side were small and showed poor development.

The scalp was not excessively adherent to the skull, but was extremely thick. The skull was greatly thinned, especially in the left parietal and frontal regions. The diploë was entirely obliterated in those parts of the cal-

Fig. 3.—The relative size of the two cerebral hemispheres is shown; frontal aspect.

cium. The dura was not excessively adherent to either the skull or the pia, and its sinuses were free. Adjacent and parallel to the superior longitudinal sinus and near its anterior extremity was found a "bear claw" bony formation firmly attached to the inner surface of the dura. It was triangular in shape, about two inches in length and partially covered the convexity of the left frontal region. The dura was somewhat thickened in some areas on the right side, while the left presented a well-formed membrane over its internal surface. There were a few small calcareous bodies in the dura. The

Fig. 4.—View of the two hemispheres of the cerebellum, showing their relative size. *a*, Small right cerebellar hemisphere. *b*, Normal left cerebellar hemisphere. *c*, atrophied convolutions of left cerebral hemisphere.

pia was considerably thickened, especially in the occipital and frontal regions of the left side, and quite adherent to the brain surface. There was considerable edema of the pia-arachnoid over the whole brain surface and many opaque areas in the pia, especially on the left side. The velum interpositum was considerably thickened. The vessels at the base presented the following abnormalities: The left anterior cerebral artery was very small and rudimentary. The anterior communicating artery was very long (three-quarters of an inch); the cerebellar branch of the basilar artery was very small on the right side.

The brain mass filled the cavity of the skull fairly well; but on attempting its removal, the left cerebral hemisphere was so greatly softened that the ventricular wall and certain pseudo-porencephalic areas on the left side were still somewhat distended. Figure 2 shows these areas collapsed and gaping, certain ones being indicated (*a*), but the largest of these cysts was located in

Fig. 5.—Drawing of section of the medulla through the inferior olivary bodies, showing atrophy of left inferior olive, *a*, and left posterior pyramid, *b*.

Fig. 6.—Drawing of section through the cervical cord, showing sclerosed area in region of right pyramid, *a*. The entire right side of the cord is smaller than the left.

the superior parietal region and is not shown in the cut. The relative size of the two hemispheres is shown in Fig. 3.

Weight of brain without pons and medulla was 586 gm., left side 85 gm., right side 501 gm. The convolutions of the entire left hemisphere were very rudimentary (microgyria) as shown in Figs. 2 and 3. Those of the parietal and occipital areas were especially small

Fig. 7.—Infantile right arm.

(knife-blade-like) and of diminished consistence. There were two convolutions in the occipital region and one in the temporal that still showed a cortical formation, but both were very small and the cortex was very thin and rudimentary. At the juncture of the Sylvian and Rolandic fissures there were several convolutions also

Figure 8.

that showed a rudimentary cortex. The entire parietal region of the left side was pseudo-porencephalic. There were two large cysts, each about the size of an English walnut, in the upper parietal region. They are shown by the fulness indicated (*a*) in Fig. 1, and the gaping areas (*a*) in Fig. 2. There was a large cyst also in the upper

temporal region of about the same size but somewhat multilobular (Fig. 2, *b*). There were many small porencephalic cysts scattered throughout the parietal and temporal regions. The lateral ventricle and the pseudo-porencephalic areas are completely collapsed and the left hemisphere appears as an undeveloped mass. The left lateral ventricle was very large in comparison with the right and its ependyma over the basal ganglia was very granular.

The right cerebral hemisphere was large in comparison with the left, the convolutions being large and coarse. Between the superior and middle frontal convolutions and at the point where they join the ascending frontal convolution there was an unusually large and gaping sulcus as shown in Fig. 1, (*c*). There was also a decided break in the ascending parietal convolution which gave rise to another gaping sulcus (Fig. 1, *e*). The sulci over the entire right cerebral hemisphere were wide and shallow and the convolutions coarse and rounded. The cortex appeared of normal thickness and

right cerebellar peduncles were greatly reduced in size, being about half the size of those of the opposite side.

The medulla was very asymmetrical. The pons appeared very narrow transversely, and was much shrunken on the left side. The left crus above was reduced in size and the pyramidal region below was very rudimentary (Fig. 5, *b*). The left olive was very small compared to that of the opposite side; otherwise the tegmental portion of the medulla on the two sides appeared about equal.

The base of the skull was markedly asymmetrical; the left anterior fossa (Fig. 8) was relatively shallower and more rudimentary in its cavity development. The left middle fossa was also smaller and of lessened capacity compared with that of the right. The superior occipital fossæ for the cerebrum were slightly asymmetrical. The capacity of the left was uniformly less in all its dimensions, while the inferior occipital fossæ for the cerebellar lobes were markedly asymmetrical. The right fossa was little more than a continuation of the basilar

appearance throughout this hemisphere, but the brain substance was somewhat congested.

The basal ganglia of the left side were very greatly reduced in size, especially the optic thalamus, which was a mere nodule. The lenticular and caudate nuclei were larger in proportion than the optic thalamus, but were, nevertheless, small. The cornu ammonis was small and greatly sclerosed. On incising the basal ganglia, the internal capsule appeared very rudimentary, appearing as a thin narrow line throughout its entire extent. The basal ganglia and the internal capsule of the right side appeared normal.

The cerebellar hemispheres were very unequal in size, the right being much smaller (Fig. 4, *a*) and weighing 57 gm., while the left hemisphere weighed 77 gm. The substance of the right cerebellar hemisphere was of greatly increased consistence, sulci shallow, convolutions small and arbor vitæ almost absent. Of its interior ganglia the dentate nucleus was still definable. The

groove, which was S-shaped. The left fossa was twice the usual size.

To summarize the points of interest in the case: We have here a very pronounced case of infantile cerebral palsy, beginning at 2 years of age, and later resulted in severe epilepsy. Mental impairment was not marked; speech and the special senses were intact and normal. The cerebral lesions were probably produced by venous thrombosis of surface veins and secondary hemorrhage resulted. This in turn caused more or less complete but asymmetrical atrophy of the entire left hemisphere (microgyria, cystic degeneration and pseudo-porencephaly). Secondly, the cerebral lesion caused mal development of the whole right cerebellar lobe and extreme atrophy of the left thalamus and inferior olive. The cranial fossæ at the base also participated in the pathologic condition most remarkably for an extra-uterine lesion. Their arrested development corresponded in location and extent with the brain masses which each contained.

## MANAGEMENT OF THE UMBILICAL CORD.\*

C. S. BACON, M.D.

CHICAGO.

The cutting of the cord is the first surgical operation to which most human beings are subjected and an operation to which all must submit. The management of the stump during its separation from the body and the care of the ulcer subsequently formed are surgical procedures upon which depend the health and perhaps the life of the infant. If the wound be improperly managed so that infection results the child comes into serious danger. Navel infection is indeed one of the greatest dangers to which the newborn is exposed.

This surgical operation has been done since time immemorial. It must also be performed by the lower animals. It was done for centuries and ages before there were surgical principles to determine its technic. It is done to-day in many, perhaps the majority of cases, by those who have no knowledge of surgical principles.

Yet in some way or other babies have generally overcome the dangers of hemorrhage and infection of the stump of the cord just as they have overcome the measles and chicken-pox and the other infantile diseases that overtake them a little later in life. Nature's protective arrangements provided for by natural selection in the ages of development are generally sufficient to overcome or ward off the dangers that confront the newborn. It is probably true that Nature's arrangements are more efficient with races in a state of nature than with highly civilized mankind. Just as plants cultivated in glass houses are not as hardy as those that grow out of doors, so people that bathe daily, live in evenly heated houses and protect themselves carefully with clothes are less capable of resisting hurtful influences than dirty and naked savages.

Nature's methods of ridding herself of offending matter and healing wounds are sloughing, suppuration, ulceration and inflammation. These suffice very well for natural conditions. In this way the stump of the cord is removed and the ulcer that is left is healed. These methods do not satisfy us entirely to-day in our civilized state. We have begun to control the processes of Nature which show in our bodies just as we have learned to control the forces outside of us. We can to some extent eliminate sloughing and inflammation from the healing process. This we do by the aseptic technic which follows from the applications of the discoveries of Pasteur and Lister. You know what a revolution the principles of asepsis have made in surgery. Is it worth while to apply the principles of the new surgery to the management of the child's navel?

Perhaps the majority of physicians would answer that the old methods of caring for the cord are good enough. By the old methods I do not mean now the primitive methods of animals and savages, that is, tearing or biting off the cord and letting the stump hang until it is separated by rapid suppuration in one or two days. The old methods to which I refer are semi-surgical methods of the ordinary nurses and midwives, namely, cutting the cord with a stump one to two inches long and keeping it wrapped in a piece of old linen and covered with oil or lard or perhaps dusted with powder till it falls away. Treated in this way the stump sloughs off in from two to six days and the ulcer, retracted below the surface of the skin, heals in a few days more. There is really very little difference between this method and what might be called the primitive method. The sup-

uration is nearly as rapid and the inflammation quite as intense.

The dangers of this method of treatment are not appreciated, because in general the importance of disturbance of navel healing in the causation of infantile disease in the first days of life is not properly studied. The management of the navel is generally left to the nurse, even when she is totally ignorant. If the temperature of the infant is regularly taken, which is rarely the case, fever is often or generally found, but this is ascribed to colic or some such cause. There is good reason for the statement that this fever is due in at least 90 per cent. of the cases to navel infection. Postmortem examinations of infants dying within two or three weeks of birth generally show, besides localized inflammation around the navel, also an arteritis, phlebitis or lymphangitis of the umbilical vessels, or all of these pathological conditions together.

It is not my purpose to give a complete résumé of the investigations in the pathology of the separation of the cord nor of the studies concerning the anatomy and histology of the cord. There is already a considerable modern literature which has recently been summarized in English by Dickinson<sup>1</sup> of Brooklyn, whose monograph is accessible to all. I will only call attention to the papers of Eroess of Budapest published in 1891, which was one of the first of the more recent papers to draw attention to the importance of this subject. He found in a careful study of cases in the Budapest clinic that the process of separation was pathologic in 68 per cent., that fever was due to navel infection in 45 per cent. of the cases, and that very serious illness and in some cases death were due to these diseased conditions. All who have given the subject any attention are agreed that navel cord separation is one of the most serious dangers that menace the newborn child and that the subject of its management is of the greatest importance.

While inflammatory changes due to bacterial presence are no doubt a constant accompaniment and factor in the separation of the cord and healing of the navel wound in a state of nature, it is possible that these events may occur without inflammation, that is, in a state of asepsis. There are three distinct physiological processes: 1, drying the cord; 2, separation of the cord from the body of the child; 3, epidermization of the navel wound. The drying or mummification of the cord is due to retrogressive changes in the Wharton jelly, resulting from lack of nutrition, combined with the desiccating action of air. The mummification makes the cord impossible as soil for bacterial growth. An impervious dressing would prevent its desiccation. Should bacteria then gain access to it there would result moist gangrene. This is often found in the stump, particularly that portion next the navel which is much less apt to mummify than the outer end. The lesson from the study of the retrogressive changes in the cord teaches that if any of the cord is left attached to the child it should be freely exposed to desiccation.

It is in the second process, that of separation of the cord, that the influence of the bacteria is in Nature's plan most efficient. There is no doubt that bacterial growth favors the early separation of the cord. Yet a sterile dried cord would in time be thrown off, when its vital connection is severed, just as a sterile blood scab is separated from an aseptic wound. The best way to remove the cord aseptically is by cutting the jelly

1. Robt. L. Dickinson: Is the Sloughing Process at the Child's Navel Constituent with Asepsis in Childbed? *Am. Jour. Obst.*, December, 1898; June, 1899.

\* Read before the Chicago Medical Society, Feb. 19, 1902

with scissors and ligating the vessels, as will be described. By using a silk ligature drawn pretty tightly around the cord at its base a considerable part of the jelly is cut through, but by this manipulation we are unfortunately often in danger of cutting through the vessels at the same time.

The epidermization of the denuded surface left by the cast-off cord will go on much better when the parts are sterile than when they are infiltrated with bacteria and their poisons. Hence, this important process is favored by surgical treatment.

It will therefore be seen that it is possible to manage the cord according to surgical principles. Suppuration, although natural and almost constant, is not necessary. These statements, probably true from our knowledge of surgical pathology, have been verified by clinical experience.

If surgical treatment of the cord is possible the prevention of infection is certainly desirable. The fact that most babies get on pretty well or at least do not die when the cord is left to Nature, which is practically what we do no matter how much we fuss with it in any of the old ways, should not satisfy us. Most women will live even if the obstetrician is not clean, but there is generally some disturbance in child-bed and at times serious trouble. Just as we have learned that the strictest possible asepsis in labor pays, so we shall find in the course of the next few years that surgical treatment of the cord will pay. I do not believe that the ideal method of managing is yet perfected. The methods that I shall shortly describe are only those that are best at present to advise for general use.

#### LIGATION.

We first ask where to ligate and cut the cord. It has sometimes been claimed that ligation is unnecessary; but the experience of all of us with hemorrhage in cases of poorly ligated cords would prevent the introduction of any practice which did not secure us against the possibility of bleeding. The mass ligature is in almost universal use and is no doubt to be advised for the use of nurses and those physicians who have no surgical experience. The objection pertains to it that in a cord of moderate size the rapid shrinking of the Wharton jelly leaves the knot loose and makes secondary hemorrhage possible. For mass ligation a narrow tape perfectly sterilized is best, as it will not be as apt to cut through the gelatinoid cord when tied very tightly as would a silk ligature. The elastic ligature has had some adherents, and ingenious devices for fastening it have been devised. Its use is somewhat complicated and the after-management is not so simple. As said above, there is no question that separate ligation of the vessels at the base of the cord is the best procedure not only because it is a sure protection from hemorrhage but also because it best favors the separation of the cord. The crushing of the cord and vessels with forceps and the use of the cautery as hemostatic have been tried but have no advantages to justify their adoption.

The cord has been tied at the junction of the skin and cord, and at all distances from the body. Unless the ligation is made close to the body of the child the best plan is to tie about 1 inch, or 2 cm., away and cut the cord 3 to 5 mm. beyond the ligature. This length of cord allows it to be laid over on the abdomen for dressing and access to the separating zone is easy. The increased length of the cord has no influence on the rapidity of its dying. If the stump is too short it will not lie well on the child for dressing and is more likely

to be pulled by the clothes and when the child nurses or is handled.

The best place for tying is, however, close to the body of the child, at the junction of the skin of the body and the amniotic sheath of the cord. When tied here and cut as closely as possible the after-dressing is exceedingly simple. The only objection is the fear of secondary hemorrhage. This is overcome almost completely by adopting the technic to be recommended. Such a hemorrhage, if it did occur, could be controlled by the nurse with pressure until surgical help could be secured. August Martin, formerly of Berlin, proposed to provide against the danger of secondary hemorrhage by severing the cord with the actual cautery, using for this that article of some ladies' toilet, the curling iron. This cauterization would also serve to remove the cord jelly or hasten its mummification and prevent infection. The danger of burning the squirming child, as well as the demonstration of the uselessness of the cauterization by the good results of the Paris clinics, where the cord is severed with the scissors after short ligation, has led Martin and his followers to abolish the cautery.

#### DRESSING.

In studying the best dressing of the cord, we must keep in mind the three physiologic changes that must take place, namely, the dying of the cord, its separation from the body and the epidermization of the surface left by the stump of the cord. Some, among others Goodell, have advised against any dressing, in order to favor the drying of the cord. That this is an important process all must admit who have seen the condition of moist gangrene and trembled over its possible dangers. Yet desiccation is interfered with only slightly by a dressing of gauze or absorbent cotton, which may perhaps help in protecting the cord from infection. Under any circumstances the impervious dressing should be proscribed.

It is essential for us to determine whether we shall strive to secure an aseptic or an antiseptic dressing. It may be admitted at once that an aseptic management of a long stump is a practical impossibility. If the duration of the management lasted only a few hours the attempt would not be so hopeless, but the most particular nurse would fail to secure asepsis in a dressing on an infant's belly for a period of three or four days. Hence, if we allow a stump at all we must be content with antisepsis and indeed with partial success. The avoidance of contamination as far as possible is of course our aim. We should be able to exclude the more dangerous contaminations such as tetanus and erysipelas germs. The saprophytes, the staphylococci and probably the colon bacilli will surely appear. Hence, the choice and method of using an antiseptic becomes an important question.

The objection to a routine and efficient use of the poisonous antiseptics like sublimate and carbolic acid are apparent. The much used boric acid is too inefficient to merit consideration. For several years I have used and advocated in my classes the use of alcohol. In 1900, Ahlfeld of Marburg, who is well known as an advocate of the practical value of alcohol as an antiseptic, published his method of treating the cord with this agent, a method which he had used for three or four years and which is essentially like my own. The method consists in thoroughly washing the region of separation of cord from the body once or twice a day with alcohol and protecting this region in the interval

with sterile or antiseptic gauze or cotton. My results agree with those of Ahlfeld in being on the whole quite satisfactory if not ideal.

Theoretically an antiseptic powder would be desirable, but practically the use of powder has not fulfilled our expectations. Iodoform is not to be thought of, on account of its odor if for no other reason. Bismuth, boric acid, dermatol, etc., are inefficient or form crusts under which the process of suppuration goes on undisturbed. Some of these powders may be of value after the cord has separated before the denuded surface is covered. For the slight eczematous condition sometimes found at this time I have often used nosophen with advantage.

Closely connected with the subject of the dressing of the cord is that of the bath of the infant. Much has been written on this subject, particularly since Doktor in Pest, following up the studies of Eroess, showed the improvement in the morbidity of infants by omitting the daily bath. It may be admitted that the tub bath is a source of contamination and in aseptic management such as we should strive for in short ligation of the vessels of the cord it should be avoided. In the antiseptic management which alone is possible with a stump it is doubtful if the bath has any deleterious effect. We must assume that bacteria begin to appear in the region of the navel in a few hours after thorough disinfection. A careful enclosure of the cord with sterile cotton will hinder the access of the germs somewhat, but in twelve hours and at least in twenty-four hours they will be found in contact with the separating cord. Now, the washing off of the cotton or gauze with alcohol and the renewed disinfection is necessary. It is not probable that the momentary contact of the bacteria in the bath water will lead to much extra contamination. The germs thus brought to the cord are at once washed away by the alcohol that is used immediately after the bath.

It is quite possible that the wetting of the cord will hinder its mummification and therefore be a further objection to the tub bath. The immediate drying of the cord after the bath and the use of the hygroscopic alcohol will, however, reduce the objectional influence of the bath to the minimum.

For these reasons I have generally allowed the bath in cases treated with a stump and have not become convinced of any deleterious effects. I always direct that the child be cleaned from all feces before it is bathed and if it has boils or pustules I interdict the tub in order that other parts of the body as well as the navel should not be contaminated.

Our observations on the antiseptic management of the navel apply to those cases where a stump of greater or less length is left. When the ligature is placed at the base of the cord and particularly when the gelatinoid envelope of the vessels is removed and the vessels ligated directly, I believe that we may strive to secure asepsis. The first method of ligation, which is that of Pinard and the one now followed by Martin and many others, may require some antiseptic treatment, for some jelly remains to mummify. The little button of jelly 2 or 3 mm. thick above the ligation is generally pulled into the navel funnel and prevents the infection of the separating junction. There can be no harm in pouring into the funnel alcohol at change of the dressing until the button separates. The aseptic dressing should protect the navel, which is no larger than after the falling off of the ligature.

When the gelatinoid envelope is removed and the ves-

sels tied directly with silk or catgut the cut vessels retract within the navel depression and aseptic management is perfectly simple. Only a dry aseptic pad over the navel is necessary. This method of management first described by Flagg, and since elaborated by Dickinson, is, I believe, very valuable and probably susceptible of general adoption.

Another method of procedure more radical than the last has been advocated by Dickinson. It consists in suturing together the skin margins of the navel after removing the cord. The vessels may first be ligated with catgut or they may be included in the grasp of the suture. Although I have not tried it, yet I mean to do so, for the suggestion is reasonable and we may find in this operation the coming method of the rational treatment of the cord.

#### MANAGEMENT OF THE CORD.

I will now briefly describe in detail the plan of managing the cord from the moment of the birth of the child. Just as the head is being expelled, a clean towel is got in readiness to wrap the child's body in the region of the cord. This towel is applied as soon as the body is born, then the child is wrapped in a large sterile blanket and laid between the mother's legs till the cord ceases to beat. It is then tied 4 or 5 cm. from the body with a sterile tape; the vessels are emptied out toward the placenta by the pressure of the thumb and forefinger of the left hand, and then the cord is held by the thumb and finger about 3 cm. away from the ligature. The cord is then cut with a sterile scissors and the placental end dropped. It is probably better not to tie the placental end unless a twin remains in the uterus. I generally cut the cord off again close to the vulva in order that an antiseptic pad may be applied while waiting for the third stage of labor. After the child is separated from the mother the body is wrapped well in the sterile towel so that the cord can not become contaminated. Then it is laid away until the mother is cared for. We then attend to the child. The nurse having prepared the room for the baby's bath, generally the bath room, by securing a temperature of about 90 F., having in readiness the bath, clothes, alcohol, cotton or gauze, scissors, artery forceps and ligature, takes the baby on her lap and holds down the arms and legs with clean towels. With sterile hands I unwrap the towel from around the cord and with a medium-size silk ligature retie the cord at its base or the junction of the skin and amniotic sheath. Without cutting the ligature I then carefully cut off the cord 2 or 3 mm. beyond the ligature. If the cord was quite thick, or if there is any sign of bleeding from the vessels, or if I have any doubt of the security of the ligature, after careful inspection, I enclose the cord once more with the ligature. The ends are then cut off rather short, and a large sponge of cotton saturated with alcohol is placed on the navel. This is kept in place by the nurse while she oils the child to remove the sebum, and then it is placed on its back in the tub that is only partly filled with water or the child is washed with a sponge. After the bath fresh alcohol is placed on the navel while the child is being dried and measured. Then a dry sterile pad of gauze or cotton is placed over the navel and the usual bandage applied. This pad stays in place without trouble till the next dressing of the child. As a rule, the child is bathed and the navel attended to every twenty-four hours. At the subsequent dressings a cotton sponge saturated with alcohol is applied before the bathing and also afterwards. Then a dry dressing is used. The ligature dis-

appears with the thin dry remnants of cord above in the funne. of the navel and is never seen until it comes off on the third to the sixth day.

The method of ligation of the vessels I have used too little to justify an opinion concerning it. My impression is that it will supersede the other method. I have performed it according to the directions of Dickinson as described in his paper before alluded to. The child is prepared for the little operation as described, and then holding the stump of the cord in the left hand we cut around the skin margin with blunt-pointed scissors. One can generally see the vein near the surface at one point. Here we must be careful not to cut the vein. The jelly is then stripped back like a cuff leaving the vessels exposed. They are then tied with a fine silk or catgut ligature and cut beyond the ligature. They at once retract and give us no further trouble. A pad is then placed on the navel and held with a bandage. The child is bathed with a sponge and not placed in a tub for a week.

These methods can not be recommended to nurses. For them I advise the procedure I myself followed until about ten months ago. The cord is cut primarily as before described, leaving a stump about 2 cm. long. After the bath the cord is wrapped in cotton saturated with alcohol, which is allowed to remain three minutes. This is then removed and the cord wrapped in sterile absorbent cotton and laid to one side and bandaged. At the subsequent dressings the cord is wrapped in alcohol-saturated cotton both before and after the bath. Care is taken to apply the wet cotton to the base of the cord at the line of the separation, for it is always at this point that suppuration occurs. In applying the dry dressing it is also carefully wrapped around the cord at the line of demarcation.

By this method of management the separation of the cord is probably delayed. It is attended, however, with no infection and that fact more than counterbalances for the delay in separation. The greatest objection to this method is the care necessary in the dressing and the inconvenience to the child, inseparable from a long stump that is apt to pull on the clothes and cause trouble.

## SOME OBSERVATIONS ON RESECTION OF THE RIBS IN EMPYEMA.\*

ANDREW STEWART LOBINGIER, B.A., M.D.

Professor of the Principles of Surgery and of Clinical Surgery in the Medical Department of the University of Colorado;  
Visiting Surgeon to the University Hospital.

DENVER, COLO.

The management of effusion into the thorax will depend much upon the character and extent of the inflammatory process which produced it. Netter has shown that in children empyema is of tubercular origin in 25 per cent. of all cases. The other 75 per cent. is due principally to the pneumococcus, with the staphylococcus, streptococcus, the Eberth and colon bacillus as occasional sources of infection. In adults Netter and Eichhorst have found 65 to 69 per cent. to be tuberculous.

It is generally recognized that empyema resulting from tubercular pleurisy has a much less favorable prognosis than when of pneumococcus origin. The latter variety of cases is attended by a less stable proliferation and the lung is left more patent and resilient than is the case in tuberculosis.

A very small percentage of cases are permanently

cured by aspiration. Da Costa believes the cures to be limited chiefly to post-pneumonia cases in children and declares pointedly that "aspiration is not to be considered a method of curative treatment in empyema."

In very young tubercular subjects of progressive type Lockwood prefers aspiration and regards it as the surgical measure of election in these cases. In fact it is the experience of most operators that extensive resection in young tubercular subjects of florid type, is not attended by results sufficiently favorable to justify the hazard of such a radical measure.

In operable varieties of empyema of long standing, where the pleura is greatly thickened, nothing but extensive resection of the ribs should be undertaken. The delay so common in these cases can offer no possible hope for the patient and only endanger his life from amyloid degeneration of the liver, spleen and kidneys.

There is a principle involved in the operation for empyema which underlies the argument for radical interference and must not be lost sight of in the consideration of every chronic case. This principle consists, not in evacuation, not in drainage simply, but in the obliteration of an abscess cavity, whose non-collapsible wall is a bony arch. This obliteration may be accomplished either by releasing the thickened pleura over the bound-down lung, as De Lorme has advocated, or if this be not feasible on account of atrophy, tubercular consolidation or fibrous contraction, then collapse of the thoracic wall may be effected by some modification of Quenu's, Estlander's or Schede's method.

It is evident that the choice of operation must be governed largely by the pathologic condition in each individual case, the long-standing cases with large cavities calling for more extensive resection than those of briefer duration.

Resection of the ribs in empyema was first advocated by Warren Stone of New Orleans. Since his day a great variety of technique has been employed, but underlying each method has been the principle heretofore enunciated.

Every chronic patient presenting himself for operation should have the urine carefully examined for evidences of amyloid degeneration. As much time as the condition of the patient will permit should be devoted to preparation for the shock, which very commonly attends thoracic surgery in depleted subjects.

If a thoracotomy has previously been done, the usual preliminary withdrawal of the greater portion of the pus will, of course, not be required. I am in the habit of waiting a week or ten days after tapping before proceeding with the resection. This affords time for the heart to return to something near its normal position and for the patient to gain resistance. The heart should be supported by strychnia a week before operating. On the table 1/20 grain should be given hypodermically, to be repeated at the conclusion of the operation if necessary; and by the rectum a liter of warm salt solution, to be followed by subcutaneous transfusion of the same during the operation, should the pulse require it. These well-understood measures of preparation and support are detailed here for the purpose of their especial emphasis, and because of a belief that often they are grossly neglected in this class of surgery.

The principle of obliteration of the pus cavity is somewhat that of the contraction of a hollow sphere. Hence the widest resection should be in a plane crossing the center of the sixth rib, and should not go higher than the second, nor lower than the ninth rib. It has been

\* Read before the Colorado State Medical Society, at Denver, June 18, 1901.

my observation that the ninth is best left undisturbed, and that whenever a pocket is left unobliterated it is commonly found to be near the apex and next to the axilla.

The U-shaped flap of Schede is much to be preferred to the straight or elliptical incisions of Pearce Gould or the intercostal incisions of Estlander. Schede's flap was designed to be followed by the total shearing away of the ribs and muscles, from the angle posteriorly to the cartilage anteriorly. But this technique may be so modified as to include an ellipse, the transverse diameter of which will measure six or eight inches, exsecting rib and periosteum and leaving the costal muscles and parietal pleura. With this modification it becomes necessary to curette the thickened parietal pleura as well as that over the lung, in order to obtain union when the two surfaces are coapted.

The procedure advocated by De Lorme whereby the thickened pleura is torn away from the lung and the latter allowed to expand, is theoretically ideal, but it is adapted only to the more recent cases where the lung is merely bound down and not extensively atrophied or consolidated. It is a procedure attended by considerable danger, and Kiliani reports the case of a little girl 9 years old, on whom he operated, who bled profusely through the mouth and nose from laceration of the lung in tearing away the densely adherent pleura.

Perhaps no feature connected with the operation and after-treatment of empyema has been more widely discussed than that of irrigation. At present most operators are opposed to irrigating either before or after the resection. Several very reputable surgeons have limited washing out the thorax to the fetid class of cases. But there seems little reason for this distinction and it may be confidently stated that an increasing number of surgeons believe irrigation to be a dangerous and needless measure. Senn wipes the cavity dry with gauze sponges, and finds in the more recent cases this to be sufficiently erosive to clear away the lymph coagula and expose the capillaries, thus avoiding the curetting required in the older and denser deposits. In the latter class of cases, however, nothing short of deep and thorough denudation will answer. No islands of lymph deposit should be left behind, for such constitute one of the most potent causes of pockets and fistula through which the discharge may persist.

Care should always be exercised to introduce the lightest possible gauze drain and to maintain perfect collapse and coaptation of the thoracic wall with the lung surface. One of the strongest arguments against the use of irrigation, aside from the danger of syncope, is the hydrostatic distension it causes of the walls designed to be in collapse.

In conclusion, it may be well to emphasize certain well-defined facts in connection with this review:

1. Cases for operation must be selected with much care and judgment and without delay for repeated or too frequent aspirations.
2. Progressive tubercular involvement in young subjects is a contraindication for anything more radical than simple thoracotomy and drainage.
3. Cases long delayed, until the organic pleura is dense and contracted, require free resection and are apt to be attended by greater deformity and loss of lung tissue, than those resected earlier.
4. The periosteum must be removed completely and the U-shaped flap affords the best covering for this, as it does for the lung in the true Schede technique.
5. Irrigation is not at any time to be employed. The

cavity may be wiped, both before and after curettage, with dry sterile gauze sponges. After this a light drain of iodoform gauze may be inserted, and the usual thick sterile dressing of gauze and cotton under snug compression by adhesive strips, placed over the resected area. The after-treatment is that of any collapsed abscess cavity, drainage being abandoned as early as possible. Firm pressure over the collapsed area should be maintained by properly applied dressings until coaptation of the flaps has been fully established and the sinus closed.

Scoliosis and drooping of the shoulder on the affected side have always seemed to me to be needlessly dwelt upon and to constitute in the average case a very unimportant sequel to resection. I can recall no case where it was sufficiently marked to be worthy of comment. Much can be done after the wound has closed to correct through proper muscular and respiratory exercises the scaphoid depression which deflects the spine and drags the shoulder downward.

McPhee Building.

### CASE OF RIGHT CECAL HERNIA, COMPLICATED BY HYDROCELE AND SUPPURATIVE APPENDICITIS.

RAYMOND CUSTER TURCK, M.D.

Professor of Anatomy and Operative Surgery, Chicago Post-Graduate Medical School; Director of the Post-Graduate Laboratory; Adjunct Professor of Surgery, College of Physicians and Surgeons (University of Illinois); Surgeon to Post-Graduate, Chicago and Samaritan Hospitals; Fellow of the Chicago Academy of Medicine.  
CHICAGO.

Mr. D. G., aged 78, was sent into the Chicago Hospital with a diagnosis of probable strangulated inguinal hernia. Patient was found suffering intense abdominal pain, and unable to pass feces or flatus; temperature was 101.4, pulse 110, respirations 34. There was no nausea or vomiting. He gave a history of having had right inguinal hernia for over sixty years, with small hernia on left side for about twenty years. He had worn a truss and had suffered no previous pain or particular inconvenience other than an obstinate constipation. Bowels had not moved for ten days previous to entering hospital. It was impossible to get a satisfactory history.

Physical examination revealed a greatly distended, generally tender, and markedly tympanitic abdomen. Hernia on left side was protruding at the external ring, about the size of a hen's egg. Right hernia was very large, scrotum extending downward nearly twelve inches. In the bottom of the scrotum was a large hydrocele. It was impossible to differentiate the testicle. Just above the hydrocele was a hard mass about the size of an orange, firmly fixed to the hydrocele sac, and entirely incompressible. Above this mass could be distinguished the presence of bowel, filled with gas, and apparently containing no fecal matter. Hernial sac and contents were hard and inelastic; the hernia could not be reduced in the slightest degree, and there was no impulse on coughing. Diagnosis was made of hydrocele, hernia probably strangulated at internal ring, with hypertrophy of sac and possible malignancy. Very slight returns of scybala resulted from enemas.

Operation was performed Aug. 8, 1901, with chloroform narcosis. A long-curved incision was made on the right side through skin from point above internal ring to the bottom of the scrotum. Hydrocele was turned out and contents evacuated by an incision preparatory to Sach's operation; hernial sac was exposed and isolated as well as possible. Sac had a diameter of over three inches, and was intimately adherent to the surrounding tissues. Upon cutting into the sac, along the anterior surface, it was found very much hypertrophied, being about three-eighths of an inch in thickness. The interior of the sac was filled with a doughy, yellowish-white, agglutinated convoluted mass of bowel adherent also to the internal surface of the sac, and to the lower tumor mass, which, at first sight,

appeared to be a carcinoma of the epididymis. It was impossible to visually or palpably demonstrate the variety of the bowel; an extreme hyperplasia of the serous and muscular coats destroyed all semblance of normal intestine. The bowel and interior of the sac were covered with a muco-purulent material of offensive odor. This secretion was wiped away and the upper portion of the bowel was protected with gauze pads. After partial separation of the adhesions, the large and small bowels were differentiated. Adhesions were broken down in the course of which a portion of the hypertrophied serous coat was stripped from the lower portion of the cecum; this demonstrated the vermiform appendix passing downward into the tumor. The appendix was ligated and cut as close to the cecum as possible. During the manipulations there was an escape of a small amount of very fetid pus from the lower part of the appendix; because of this, and because of the agglutination of the appendix, testicle and hydrocele and hernial sacs, it was decided to remove all *en masse*. All adhesions of bowels up to the internal ring were broken down and tied off and a large amount of much thickened omentum cut away at this point, and after a careful toilet, the intestines were replaced in the abdominal cavity. The spermatic cord was ligated and cut; the hypertrophied hernial sac was cut away flush with the internal abdominal ring, and removed, together with the appendix, testicle and hydrocele sac. The internal ring was closed with interrupted sutures of catgut, and the internal oblique and transversalis muscles and conjoined tendon sutured to Poupart's ligament well down to the pubic spine. United the separated external oblique aponeurosis, obliterating the external ring, and closed the skin with silkworm gut, inserted silkworm gut drainage in the upper and central portions of the skin wound, and packed the scrotum with iodoform gauze. On account of the exhausted condition of the patient, did not operate on small hernia on left side.

Patient was given 1000 c.c. of normal salt solution subcutaneously on the table. He returned from the operating room in a feeble condition; temperature 100.2; pulse 106, intermittent; respirations 44. Sulphate of strychnia, gr. 1/30, was given hypodermically every two hours, and one pint of normal salt solution at a temperature of 115 per rectum, every three hours. He had fair bowel movement; was very restless during the night.

August 9: In much pain, vomiting and hiccuping severely. Abdomen distended and tender; slight bowel movement; some flatus passed; average temperature 100.2; pulse 96; respirations 34.

August 10: Normal salt enemas were discontinued; there was slight bowel movement. Temperature 100; pulse 85; respirations 36; severe pain, with great abdominal distension; much weakness.

August 11: Hot turpentine stupes were kept constantly on the abdomen; there was some vomiting and hiccup. He passed a little flatus, temperature not running above 99. Predigested beef 5ss was given every three hours.

August 12: General condition improved. There was no return from enemas; vomiting and hiccup were lessened.

August 13: There was slight bowel movement, with escape of a great deal of flatus. Abdominal distension was much reduced. Dressed wound, removed gauze and silkworm gut drains. Wound suppurated superficially; was repacked with iodoform gauze.

August 14: Vomiting and hiccup disappeared. There were four free bowel movements; no abdominal distension or pain; hot turpentine stupes discontinued. General condition was much improved; predigested beef continued. Temperature averaged 99; wound discharged freely at upper and lower angles.

Second week: Wound was irrigated and dressed daily, still suppurating and discharging freely. Drainage was inserted beneath skin from the upper angle to the center of the wound, and from the center to the lower angle. General condition was good, temperature averaging normal.

Third and fourth weeks: Wound still suppurated in lesser degree; sinuses beneath skin gradually closed; daily dressings, and through-and-through irrigations were continued. Bowels moved freely.

Fifth week: Temperature was normal or slightly subnormal; wound still discharged, but nearly closed. Bowels were in good condition.

Patient left hospital at the end of the seventh week; walking about; wound closed except very small superficial sinus, with no sign of return of hernia. Two weeks later patient reported wound entirely closed, with no return of hernia. He is doing daily work without a truss or any form of supporter.

The specimen was submitted to Dr. W. A. Evans for examination, who reported as follows: "Gross appearance: The specimen consists of a testicle with much thickened tunics and hydrocele and peritoneal sacs. The spermatic cord is very hard and tortuous, winding over surface of sacs (hydrocele and hernia). The exceedingly thick peritoneal sac contains an appendix which in its upper portion has its submucosa and mucosa stripped from the muscular tunics. The lower part has an enormously developed muscular tunic, and is embedded in a mass of old scar tissue. There is also some omentum greatly thickened. Sections were made of appendix at tip, and proximal end of the intestine. Microscopically, the appendix shows hyperplasia in the mucosa, submucosa, muscle tunics, and in the outside fibrous coat. There is an acute inflammation engrafted upon a chronic one. The vas deferens shows an enormous hyperplasia of fibrous tissue. There is no evidence of malignant disease."

The hernia evidently had been unreduced for a long period of years. The adhesions of the appendix to the lower portion of the sac and testicle, and numerous bowel adhesions resulting from an extension of appendical inflammation necessitated an intense peristaltic action in the misplaced bowel, with great hypertrophy as the result.

## A NEW METHOD FOR THE REMOVAL OF INTERNAL HEMORRHOIDS UNDER LOCAL ANESTHESIA.

THOS. CHAS. MARTIN, M.D.

President of the American Proctologic Society, Proctologist to the Cleveland General Hospital, Professor of Proctology in the Cleveland College of Physicians and Surgeons.

CLEVELAND, OHIO.

The subject of hemorrhoids often prefers to bear those ills he has than fly to that relatively desperate refuge afforded by general anesthesia and be relieved. As a consequence he may become a crank or an invalid. He receives little sympathy and less help, often.

The non-malignant anal growths may be removed painlessly without resort to general anesthesia by means of the technic presently to be described, provided it be performed by the trained hands of an operator who thoroughly understands the principles of infiltration-anesthesia, and who, furthermore, has been sufficiently persevering to master the difficulties encountered in the application of these principles to this operation.

The clamp, Fig. 1, consists of a hollow cone three and one-quarter inches in length and three-quarters of an inch in diameter at its distal extremity, and one and three-quarter inches in diameter at its proximal end. One quadrant of the cone is fenestrated, Fig. 3. This is occupied by a movable blade with a serrated edge, which makes contact with the cone's serrated edge. The movable blade is sheathed in the cone when the jaws of the clamp are separated. Hence, after the instrument is introduced it may be made to receive the pile without irregularly expanding the anus. The great essential to painless manipulation of the sphincter is the even distribution of pressure throughout its circumference. Users of irregularly dilating speculums have been confused and baffled by the pain they provoke.

Preparation of the patient consists in daily gradual dilatation of the anus by means of Kelly's conic dilator until the anus may be made to open painlessly to the

degree necessary for the introduction of the clamp. These patients who long have been subjects of hemorrhoids have a dilated or relaxed sphincter, and therefore do not require this preparatory treatment.

The patient should be placed and made comfortable in Sims' posture. The table's upright knee-piece should be adjusted to support the patient's legs, and the light focused on the field of operation.

The anoscope should now be employed that the precise situation of each hemorrhoid may be determined. These should be noted as occupying certain given zones and quadrants of the anus.

The summit of each tumor should be infiltrated with a one-tenth of one per cent. solution of eucain. A very fine needle should be employed. The needle should have a long tapering point; its introduction provokes little or no pain, and the thin wall of a varicose hemorrhoid may be infiltrated. Whereas, on the other hand, a needle of larger diameter will enter the tissues less easily and

The operator should take the well-lubricated clamp, adjusted as shown in Fig. 2, and introduce it into the anus with its blade pressing against the tumor which first is to be removed. When the instrument is buried to its shoulder the fenestrum should be opened, as shown in Fig. 3. The hemostat, which is attached to the tumor within the now exposed field, should be used as a lever to drag the hemorrhoid into the clamp's chamber. The pressure incident to the introduction of the clamp often expresses the eucain from the tumor so that it is necessary to re-anesthetize it before subjecting it to such manipulation as is necessary to carry it completely into the clamp. As the pressure of the clamp from this time on obstructs the local circulation, the infiltration should be thorough. Not only must the tumor itself be anesthetized, but its base also, and the tissues underlying this. If the patient should feel pain at any time during these manipulations, it indicates that the infiltration is incomplete—complete it. The clamp

Figure 1.

Figure 2.

Figure 3.

will provoke great pain, and perhaps may be so much thicker than the capsule of the tumor it is designed to anesthetize, that instead of effecting an infiltration of that structure the anesthetic may be driven at once into a blood-space and directly into the circulation.

The now artificially edematous and anesthetized portions of the several tumors should be grasped with curved hemostats and the anoscope withdrawn. It will then be noticed that the tumors are somewhat prolapsed under the weight of the pendant hemostats, and that because of their handles the anoscope can not be drawn off them. They should be detached, withdrawn from the anoscope and reattached, one by one. Thus, in order, each of the prolapsed tumors is to be released and again seized and the anoscope removed from field of operation.

The attached hemostats should be surrendered to an assistant, who should radiate them from the anus and well out of the way of the operator.

should now be closed and locked, and the growth cut away by means of scissors.

If the character of the growth is such that the operator has reason to fear secondary hemorrhage, the wound should be lock-stitched with catgut. If it be of the connective-tissue or fibrous variety the pedicle should be cauterized. The red-hot platinum should be applied for a second only and repeatedly, thus the clamp will not accumulate sufficient heat to distress the patient, and the lymph will be coagulated and plug the vessels.

Tentatively, the clamp should be made to release the wound. If there be any bleeding it may be controlled at once by suture or cauterization.

The clamp should be withdrawn gently and reintroduced for the removal of other hemorrhoids, if necessary.

This clamp may be separated and rendered aseptic—Figs. 4 and 5. As the tumor operated on is within a sterile metal chamber, the former may be antiseptized,

and, therefore, the field of operation may be rendered surgically correct. Insulation of iodoform or other antiseptic powder upon the wound fortifies it in a measure against subsequent infection.

Because of its peculiar form this clamp effectually

Figure 4.

blocks the field of operation against the accidental invasion of feces or the remnant of an enema. There can occur no hemorrhage to inundate and obscure the field. The pile is dry-docked.

Figure 5.

This clamp demands that the wound shall be linear in form and parallel with the axis of the anus; it dilates the anus to a degree greater than its normal excursion,

hence there will be no subsequent contraction and stricture as a result of this operation.

That this method of clamp operation is inapplicable to inflamed or thrombotic piles, is obvious.

Eucaïn is much less toxic than cocaine. Eucaïn may be sterilized by boiling without affecting its anesthetic property. An ounce or more of a one-tenth of one per cent. solution may be used without danger, for on the removal of the tumor most of the eucaïn is recovered. If the eucaïn be prepared in normal salt solution its injection is not so likely to be followed by smarting and burning.

Local anesthesia is a surgical refinement; skill in effecting it may be acquired only by the exercise of patience and practice.

729 Case Avenue.

### A METHOD OF SUTURING THE GALL-BLADDER TO THE PARIETES IN GALL-BLADDER OPERATIONS.

WILLIAM WOTKYNs SEYMOUR, A.B. Yale, M.D. Harvard.

SURGEON TO THE SAMARITAN HOSPITAL.

TROY, N. Y.

In my last twenty cases I have attached the gall-bladder to the parietes in the following manner: A

full curved Hagedorn needle is threaded with silkworm gut and passed mattress-stitch fashion from within the gall-bladder through the peritoneum, overlying muscle

and fascia; then it is brought out and reintroduced and carried out through the skin a short distance from the wound. The opposite end of the silkworm gut is introduced in the same manner and the ends fastened by two or three shot, the uppermost of which is crushed. At first I used five sutures of this character to suspend the gall-bladder, but now I rarely use more than three. The suspension sutures are removed on the tenth day, or earlier, if indicated. The advantage in this form of suture is that there is no danger of the sutures falling into the gall-bladder to become the nidus of new concretions as in the cases reported by Homans, Kocher and Kehr, and the early removal of the sutures relieves the patient of the annoyance of the extrusion of unabsorbable sutures weeks after operation. In no instance have I had a fistula and the healing has been as prompt as was desirable in each case. In closing the abdominal wound I prefer the through-and-through suture of silkworm gut, at least three to the inch, passed so as to take in little peritoneum, a good grip of the muscle and fascia and very little skin, and not drawn very tightly. The time required is very brief and the joint a sufficiently light one.

## GLIMPSES OF THE PRACTICE OF MEDICINE AND SURGERY IN BRITISH AND SPANISH HONDURAS.

N. SENN, M.D., PH.D., LL.D.

PROFESSOR OF SURGERY, RUSH MEDICAL COLLEGE,  
CHICAGO.

The physicians in sparsely settled tropical countries have many disadvantages, difficulties and hardships to contend with unknown to their colleagues in prosperous countries in the temperate zone. They are isolated from the great centers of medical education, and the benefits arising from professional intercourse and attendance upon active medical societies. The defective mail service interferes with the regular supply of recent medical literature. The physician in remote country and coast towns is often thrown upon his own resources in the treatment of grave cases, as satisfactory counsel is frequently unavailable. He is seldom adequately remunerated for his services as the majority of those who apply to him for aid are too poor to reward him for his work. In many instances he furnishes the medicines or dressings without any expectation of a return of his cash outlay. If he is not in possession of an unusual degree of energy, he soon falls into a routine practice and finds himself in a few years far behind the rapidly advancing medical progress. Exposed to the depressing effects of a tropical climate, he leads a life which is not conducive to scientific research and professional advancement. It is under such circumstances that encouragement from outside sources often succeeds in stimulating the lagging professional and scientific interests. The occasional medical journal or some new medical book sent to these distant colleagues is always appreciated and its contents eagerly devoured.

### CHARMING VACATION SPOTS.

Central America is an ideal place for a midwinter vacation, and it is somewhat strange that it is so seldom visited by our medical men who need rest for a few weeks at that time of the year. It is very accessible and can be reached from Chicago with comfort and ease in less than a week. The steamers of the United Fruit Company sail from New Orleans for the different ports every week. The voyage of five days is a restful one, admirably adapted for mental recuperation and physical rest. The gradual transition from ice and snow to a tropical climate is an experience well calculated to divert the channel of thought from the bedside and operating room to Nature's wonderful products and works of art. To leave ice-bound Chicago and find yourself ten days later shooting monkeys and parrots in the primitive forests of Spanish Honduras is an experience it would be impossible to duplicate by

traveling the same distance in any other direction. The dangers of contracting malaria or any of the tropical diseases, if one observes the ordinary precautions, is very remote. All of the Central American countries present scenery, inhabitants, antiquities, trees, shrubs, flowers, fruits and birds that daily furnish new object lessons for the study of the visitor from the north. The gigantic trees, the flowering shrubs, the birds of song and plumage, the antics of the monkeys in the tree-tops, the humming of insects, the immense fields of the stately banana, the magnificent coffee plantations on the hillsides, with the dark shiny green leaves of the shrubs bearing the snow-white fragrant blossoms and the purple berries, can not fail in fascinating the thoughts of the traveler. The mixture of races and the habits of the people are studies in themselves. To the medical man the study of tropical diseases and climatic conditions are of special interest. He will find in all of the larger cities physicians well prepared and willing to give detailed information on these important subjects.

Last winter I visited Costa Rica and reported the results of my observations in the columns of THE JOURNAL; this year I selected British and Spanish Honduras as the objective points of my short midwinter vacation. Last year the trip was made in January, this year in February. In comparing my experiences, I have come to the conclusion that January is the best time to visit any part of Central America, as the summer here begins during the month of February, with a marked increase in the temperature.

### BRITISH HONDURAS.

This is one of the smallest colonial possessions of Great Britain. Since it came under British rule it has been free from strife and rebellion. The colonial government is a wise and efficient one and insures justice to natives and foreigners alike. The whole population does not exceed 39,000, of which number the whites number only 800. Belize, the largest city and the seat of government, has a population of 10,000. The coast is low and swampy, the interior mountainous. The principal articles of export are mahogany, cedar and bananas.

### PHYSICIANS.

The practice of medicine is regulated by a board of medical examiners composed of three members appointed by the government. Examination is compulsory. Applicants must present a diploma from a recognized medical college. At present there are only seven licensed physicians in the entire colony, one of them a woman, a graduate of the College of Physicians and Surgeons, Chicago. The most prominent doctors in the capital city are Drs. Eyles, Harrison and Heusner.

### HOSPITALS.

The colonial government has made adequate provision for the indigent sick by the establishment of three hospitals. The Belize Public Hospital has 43 beds and at the time of my visit every bed was occupied and a number of cots furnished accommodations for the overflow. During the year 1899, 429 cases were treated in this institution. The two-story buildings are constructed of wood and the wards are fairly well furnished. The operating room is small but well lighted and supplied with the most necessary instruments and appliances for aseptic work. Dr. J. H. Harrison is in charge of the hospital and at the same time attends to the insane asylum, poor house and prison, which means hard work. For all of this he receives the pitiable salary of \$1000 a year. Dr. C. H. Eyles, the colonial surgeon, for good reasons, takes great pride in the commendable fact that the colonial government sets aside 10 per cent. of the entire income for the medical department, something that can not be said of any other government in the world. The nursing in the hospital is done by colored women and two colored orderlies trained by Dr. Harrison. The first attempt to secure trained female nurses for the hospital was made in 1894. At first this was in the nature of an experiment, but as it proved to be successful the same plan has remained in force with the most satisfactory results. The female nurses remain in training for one year and when found satisfactory at the end of this time receive a salary of \$7 per month and board and washing. The orderlies are paid from \$240 to \$480 a year. They assist in oper-

ations, dispense the medicines and do part of the nursing in the male ward. The scrupulous cleanliness of the wards, bedding, patients and halls speaks well for the nursing force of this institution.

Dr. Harrison is an enthusiast in his hospital work and chafes under the somewhat primitive conditions under which he has to labor. There can be no doubt but that under his wise and energetic administration the institutions will grow and improve in the course of time. Everything in Central America under the care of man moves slowly and the hospital work constitutes no exception. The public takes very little interest in charitable institutions and the entire responsibility rests in the hands of the government, which certainly has shown its liberality towards the medical department in a way that should humiliate more prosperous nations.

The two remaining hospitals have each a capacity for about sixteen patients, are located in the coast cities next in size to Belize and are likewise supported by the government and are in charge of competent physicians. From the above it will be seen that the government takes care of 75 sick poor and the whole number treated at public expense will reach annually in the neighborhood of one thousand patients.

What Belize needs is a small, well-equipped private hospital for the accommodation of foreigners and well-to-do citizens. The enterprising United Fruit Company and the prosperous merchants of the city should take the necessary steps in this direction, as such an enterprise would soon become self-supporting and would do away with one of the objections on the part of the travelers who visit this country, in case of accident or sickness.

#### INSANE ASYLUM.

On the same grounds and only separated a few yards from the public hospital, stands the insane asylum, occupied at present by 46 inmates, 31 males and 15 females. It is a one-story wooden building resting on piling five feet above the ground. The rooms are kept clean and patients are well treated and well fed. If a person is found insane he is admitted without any court proceedings. The prevailing type of insanity is melancholia, although the homicidal and suicidal forms and violent outbreaks are by no means rare. Dr. Harrison believes that alcoholism is the most potent cause in the production of mental disorders. Caribs, Indians and the mixed populations furnish the largest contingent of mental diseases. Drunkenness is very common. A cheap vicious rum made of sugar cane is the national drink among the common people.

#### THE PRISON.

This is a modern building surrounded by large grounds with palms and flower-beds and fenced in by a high solid stone wall. An English officer is in charge of the prisoners and enforces strict discipline. The treatment is humane. The cells are kept scrupulously clean and the food is excellent. Most of the prisoners are serving long time sentences and are employed in manufacturing mats and brushes from the fibers of the envelope of the cocoanut, shoemaking, tailoring and crushing stone. A few of them are engaged in printing. There has been in many years only one execution by hanging. The execution chamber is in the prison building and the trap is always kept in good working order. Corporeal punishment seldom becomes necessary, as was evident from the brand-new appearance of the different implements of torture that were shown us on our visit. The prisoners numbered 43, one, the most dangerous one, being an American. Most of them were committed for murder, robbery and stealing. The fact that only one woman was in confinement speaks well for the good behavior of the female population. This prisoner was a girl, 18 years of age, of doubtful racial origin, who awaited trial for stealing.

#### MIXTURE OF RACES.

British Honduras is a small country with a still smaller population, but it is one of the best places to study racial mixture. In visiting the market, the different places of business, and in observing the passers-by in any of the public thoroughfares, the visitor can see in a short time all shades of color from coal-black to the fairest of the fair, the short

curly hair of the negro and the long, straight jet-black hair of the pure Indian. The Indian and the Carib represent the early settlers of the country. Then come the English, French, Germans, Americans, Spaniards, Portuguese and the American and Jamaica negroes and the mixtures arising from intermarriage between the different nationalities. The Carib maintains his identity more than the native Indian as he is opposed to intermarriage. He bears a strong resemblance to our negro and is undoubtedly of Ethiopian origin. The Indian mixes freely with all nationalities. The intermarriages which have taken place between the native Indian and the different white races since Columbus discovered this part of America and the invasion by that intrepid explorer Cortez have resulted in a mixture of races such as it would be difficult to find to the same extent in any other country. Such a mixture of races has its advantages and disadvantages. It is one of the means of spreading civilization, but leads at the same time to vice and disease. The natives of Central America have and continue to share the same fate that was meted out by the whites to the North American Indian. He is losing his right-

Mixture of races.

fully inherited landed possessions and has acquired from the European invaders more of their vices than their virtues.

#### PREVAILING DISEASES.

British Honduras, like all other Central American countries, has its share of malaria, the most prevalent disease. The lowlands along the coast are the breeding-places of the plasmodium. Many of the residents, foreign and native, who have lived for several years in malarial districts show plain indications of chronic malarial poisoning. The pernicious form and that complicated by hematuria are occasionally met; the quotidian type is the most common. Yellow fever has never had its origin here, the several epidemics which have scourged the country at different times could always be traced to cases coming from Cuba, Port Limon or South America, more especially Colon. Tuberculosis is prevalent among the Indians, Caribs and halfbreeds. The lungs are most frequently the primary seat of the disease, but glandular, bone and joint tuberculosis are by no means rare. The mixture of races has here, as elsewhere, been a potent element in the rapid dissemination of the disease. Pneumonia and rheumatism are most common during the rainy season. Dysentery and diarrhea occur at all times of the year and to them must be attributed the frightful infantile mortality.

The frequency of intestinal disorders can be accounted for by improper food, inadequate clothing, exposure to rain, prolonged heat and high atmospheric humidity. The maximum shade temperature is about 90 F., minimum, 56 F. Whooping cough invaded the colony in October, 1898, has continued to prevail from time to time and has contributed largely to the mortality of infants, and raised the death rate from respiratory diseases. Typhoid fever is a very rare disease here as elsewhere in Central America. The rarity of the disease in Belize may be attributed to the water supply as this is on the "separate" system, that is, to a considerable extent each house has its supply from a separate vat, the water being

rain water collected from the roof. A few years ago there were four cases of leprosy in British Honduras, at present only one.

Anchylostoma was reported for the first time in the colony in 1898. Since that time it has been frequently observed. I was given an opportunity to examine two cases in the Public Hospital. In both instances the disease was characterized clinically by puffiness of the face and pronounced anemia.

In Corosal "it was observed in selected cases that this worm was almost invariably present, associated with ascaris lumbricoides and oxyuris vermicularis"; and in Orange Walk the medical officer reports: "It is frequently encountered, and in responsible for much of the anemia prevalent among the Indian population." (Eyles.) Cases of beri-beri are occasionally seen both imported and indigenous. One case of this disease, the paralytic form, is in the public hospital at the present time. The patient is a woman of middle age. The muscles principally involved are the extensors of the hand and fingers.

(To be continued.)

## Clinical Report.

### A CASE OF ATROPIA POISONING, WITH HIGH TEMPERATURE AND RECOVERY.

L. L. BEEHLER, M.D.

CHICAGO.

The patient, aged 25, was a neurotic female. She has had scarlet fever, and had studied diligently for proficiency upon the piano from early life, and was subject to severe headaches since menses were established at 15. Her father died of tuberculosis; mother, of cancer of uterus. A sister had chorea; two sisters were exceedingly irritable.

She came under observation Jan. 14, 1902, complaining of gastric disturbances, headaches, languidness and general malaise. In about a week she said she was all right in regard to previous trouble, but complained of strange noises and delusions. She seemed conscious of these troubles and said she tried to avoid them, but found it impossible. She appeared then to be a neurasthenic of pronounced type. At that time her sister was told of the possibility of acute melancholia developing, which derangement occurred one week later. At the time of the melancholia developing, care was advised as to her being left alone on account of suicidal intent. She was put to bed, and during the absence of her sister who had been sent to get her a drink she swallowed three grains of atropin in four ounces of water given her by an oculist, who had given directions for five drops in each eye every hour. The patient was seen in less than twenty minutes after taking the drug. She was given strychnin hypodermically, grain 1/40, and dose was repeated in 15 minutes on account of countless thready pulse. Apomorphin, grain 1/10, repeated in 15 minutes, gave no result. In 30 minutes 1/8-grain of apomorphin was given, with no result. Twenty grains of copper sulphate were given, with no result. A stomach tube was tried, but could not be passed, owing to constriction, which held the tube after striking the pharynx. Pilocarpin, the physiologic antidote to atropia, failed to produce any desired effect and was early discarded.

At 8 p. m. her pulse was 160, which dropped to 155 in 20 minutes. The nurse sponged the body with alcohol and water. She was later wrapped in hot towels, but diaphoresis could not be established. At 9, her temperature was 105 axillary, pulse 152. At 9:50, axillary temperature was 106, pulse the same as before. Apomorphin, grain 1/4, was then given, but with no result. At this time, the peculiar red rash appeared, first on chest. This remained for three days. One hour later her temperature had dropped to 103.5, pulse 150. At this time she was catheterized and the urine saved. Analysis later showed: Amount, 4 ounces; sp. gravity, 1.016; slight amount

of albumin. Atropin was found in urine four hours after ingestion. One drop of the urine dropped into the eye of the household cat produced mydriasis of pupil in five minutes. At 11:40, temperature had fallen to 101.8 axillary, pulse 150. At 3:40 a. m., pulse was 140, respiration 30, temperature 101. At this time patient seemed to be conscious when aroused and answered questions by shake of head. At 8:15 a. m., temperature had dropped to 98.8 by mouth, pulse 108, respirations 24. She was given one-fourth glass of milk and one dram of whisky, which she retained. At noon she urinated voluntarily and drank two-thirds of a cup of strong coffee.

Improvement was rapid up to the sixth day, with temperature normal, pulse 80, respirations 20. On the fourth day, her temperature dropped to 97, and there remained for one hour, but speedily retained its usual height under massage. On the fourth day also she started to menstruate, which at this time slightly aggravated the symptoms. Menses are usually absent in attacks of melancholia, and strange to say she menstruated two days longer than usual. The pupils were dilated before taking the atropin internally from the previous local eye treatment, hence nothing can be said in regard to them. They resumed their normal size, reaction to light and accommodation in sixteen days from ingestion of drug. Facial lividity, which is not seen as a rule except in imminent peril, was present from first and lasted two days.

The rise of temperature due to increased heat production from influence on nerve centers was combated by sponging. The fast heart due to paralysis of peripheral inhibitory nerves and to stimulation of heart and ganglia was controlled by the strychnia, which moderated it and produced a regular rhythm.

It is not possible in this case to state how long the temperature was 105 or 106 axillary, as the thermometer was not used until about one and one-half hours after the ingestion of the drug.

**The Nemesis of the Placebo.**—A famous French physician of the Second Empire is said to have given the following prescription to a hypochondriac patient who worried him:

|                          |      |
|--------------------------|------|
| R. Aqua fontis .....     | 100  |
| Illa repetita .....      | 40   |
| Eadem stillata .....     | 12   |
| Hydrogeni protoxyd ..... | 0.32 |
| Nil aliud .....          | 1.25 |

One drop thrice daily. This elixir, it is said, cured a large number of neurotics about the court and in Parisian society. But it got the doctor into trouble at last through the indiscretion of a pharmaceut. A *grande dame de par le monde*, as Brantôme would have called her, who had taken it for years with blind faith and unfailing success and recommended it to her friends as an infallible remedy for most human ailments, in an evil hour allowed herself to give way to the curiosity which proved the ruin of Eve. Consumed with eagerness to know the secret of the composition of the wonderful panacea, she submitted the document containing the mysterious formula to all the initiated whom she came across. At last she found one who revealed the fatal secret. What explanation the physician attempted is not recorded, but there can be little doubt that the outraged lady explained her attitude in language more picturesque than polite. A more modern instance of the nemesis of the placebo occurred not many years ago to a well-known practitioner in this country. He had a patient, a neurotic lady, as exacting as such patients can often be. He had at one time given her some opium pills, to which she became too much attached, and he finally decided to give her no more. On the following Sunday evening while sitting at table after dinner he received an urgent letter either to come at once or to send some more of the pills. He sent the servant to the surgery for a pill box, and there and then rolled some pills from the crumbs on the table. He received a grateful letter of thanks stating that the pills had produced the much-desired sleep, and asking for the prescription; this he declined, and was much pleased with himself on the whole. But his gratification was diminished a few mornings later when at 2 a. m. he was roused from sleep to send another supply.—*British Med. Journal*.

SATURDAY, APRIL 26, 1902.

## CRITICISMS OF SOME SURGICAL TENDENCIES.

If a single writer had announced the discovery of certain undesirable tendencies in the workings of surgery and had offered criticisms thereon, it would not have awakened much surprise. When, however, during the past eighteen months, several men of high standing in the profession both in America and England have pointed out what they believe to be a tendency for general and special surgery to overstep its legitimate limits, it surely behooves the medical profession to look at the matter impartially but very carefully. For some time part of the profession has believed that there was too frequent recourse to operative measures, especially in the surgical specialties having to do with the nose and throat and with diseases peculiar to women. The too early and frequent use of obstetric forceps has been spoken of with disapproval. Resort to exploratory incision for purposes of diagnosis in intra-abdominal diseases has undoubtedly become too common. Such an operation should be performed in rare cases only. An operation is not a legitimate diagnostic measure, save in very exceptional instances. It should never be allowed to substitute for a lack of skill in applying legitimate diagnostic means.

In August, 1900, Frederick Treves,<sup>1</sup> in the address in surgery before the British Medical Association, said that there is some foundation for the impression that operations are becoming too frequent and that, while the value of exploratory incision is beyond question, it is impossible not to notice a tendency to resort too readily to this means of arriving at a diagnosis.

At the meeting of the same association, one year later, James F. Goodhart,<sup>2</sup> in the address in medicine, spoke still more emphatically in a similar vein. He said: "Throats and noses suffer terribly from this lust of operation that has beset the public, ears are now being swept into the panic and I incline to think that the only region of our art that preserves its proper decorum is that of ophthalmic surgery." Sir Felix Semon,<sup>3</sup> in two very able lectures dealing with the principles of local treatment in diseases of the upper-air passages, maintains that the frequency with which local interference is advised and practiced nowadays is unfortunately far in excess of actual requirements; that operations are performed wholesale where they are not needed;

that operative proposals are being made and carried out on an extensive scale on the basis of some unproved theory; that the operative interference is often unduly severe and protracted in proportion to the smallness of the complaint for which it is undertaken. Coming from a man of good standing in the particular specialty of which he speaks, these criticisms can not be ignored.

Under the title of "Some Surgical Tendencies from a Medical Point of View,"<sup>4</sup> Reginald H. Fitz of Boston has written one of the most convincing articles bearing upon this matter. Speaking of exploratory laparotomies, which he thinks are too common, he says, "They are not without considerable danger and often disclose conditions which can not be relieved and which might have been appreciated without an operation. They tend to make the physician superficial in observation, since the diagnosis is to be made definitely by means of the operation." He has tabulated the cases of exploratory laparotomy performed in the Massachusetts General Hospital from 1890 to 1899. The table shows that while the percentage of deaths has grown somewhat less, being about 36, the cases which have been uncured or unrelieved remain at about 80 per cent.

The cases of cancer of the alimentary canal which were operated upon in the same hospital and whose subsequent history could be learned are also considered by Fitz; 54 per cent. died within a month and 72 per cent. within six months. Any considerable prolongation of life applied to less than 30 per cent. and to many of these the life was one of suffering and sorrow requiring the frequent or constant use of opiates to obtain any measures of relief. Of 10 cases operated on for intra-cranial tumors all were dead within eight months. He naturally questions the utility of operating in such cases.

William B. Coley of New York,<sup>5</sup> who is a surgeon, insists upon the necessity of a knowledge of the after-history of all operations in order to come to any conclusion regarding their value to the patient. He says that he has "personally observed at the Hospital for the Ruptured and Crippled many women with large and uncontrollable ventral herniæ resulting from operations that, according to the patients' stories, were performed for the relief of trifling uterine and ovarian symptoms with the result that in many cases the symptoms of the original trouble continued and in addition the patient suffered far more from the hernia that followed the operation."

Recovery from an operation does not make it a success. It is only useful when it makes life longer and more free from suffering. We can not better conclude than by quoting from Fitz: "Any operation which does not better the condition of the patient must be regarded as a therapeutic error. Progress in the future is likely to depend much more upon the discoveries which shall make surgery less necessary than to the opening of new fields for surgical treatment. The advance should be in the

direction of limiting those unnecessary and harmful operations, for the wisdom of the surgeon should serve as well to restrain him from operating as to enable him to operate successfully. Especially to be cultivated for this purpose are greater accuracy in diagnosis and prognosis and the more widespread knowledge of pathology and pathologic anatomy. The surgeon will thus become a better adviser although the number and variety of his operations thereby may materially be lessened."

#### SECOND ANNUAL REPORT OF THE HARVARD CANCER COMMITTEE.

In the second report of the Cancer Committee to the Surgical Department of the Harvard Medical School,<sup>1</sup> are given the results of a number of investigations bearing upon the parasitic theory of the origin of cancer. In the summary of the work given by Edward H. Nichols at the conclusion of the report, the plan of the investigations is made clear. Thus it has been claimed by the adherents of the theory of the parasitic origin of cancer that coccidium oriforme and other protozoa may produce a proliferation of epithelial cells analogous to that of carcinoma. This question was studied by E. E. Tyzzer, who devoted himself to an investigation of coccidium infection of the rabbit's liver. Tyzzer shows that the lesion of coccidium oriforme is essentially a chronic inflammation which in its progress and termination is not at all analogous to that of carcinoma.

It has been claimed further by the believers of the parasitic origin that the skin lesions of molluscum contagiosum characterized by epithelial proliferation, are due to the action of a so-called protozoön. Charles J. White and William H. Robey, Jr., carefully review the literature of molluscum contagiosum and report the results of an examination of several of the nodules found in this disease. The main conclusion is that the so-called molluscum bodies are composed of keratin which is produced by a strange metamorphosis of rete cells. The bacteriologic examination resulted negatively. At all events the lesions are not analogous to the processes observed in cancers.

Joseph D. Weis made a systematic study of a number of blastomycetes, including those which San Felice and Plimmer isolated from carcinoma, with a view to determine their proper place in the classification of yeasts and allied fungi. After going over the subject in the light of Klöcker's classification, which is accepted by the great Danish authorities Hansen and Jörgensen, he reaches the opinion that the so-called "blastomycetes" of San Felice and Plimmer are *Torulæ*. The subject is at present of too special an interest to be of much importance to physicians in general, but it has been evident for some time that systematic botanic study of the organisms generally referred to as blastomycetes by pathologists is highly desirable.

San Felice, Plimmer and others have claimed that by experimental inoculations of animals with blastomycetes

true carcinomas may be produced. This question was studied by Edward H. Nichols by means of extensive experimental inoculations of animals with the blastomycetes of San Felice and Plimmer, and the sum and substance of this work are that the lesions produced by these organisms are nodules of granulation tissue, consequently not cancerous or true tumors in any sense. Blastomycetes are not constant in the malignant tumors of man. Hence there is no evidence that blastomycetes have anything to do with the production of human cancers.

The endocellular bodies of cancer cells, familiar to every student of the morphology of cancer cells, have been urged by many to be parasites, and the cause of cancer. Greenough finds similar "parasites" in non-cancerous disease of the mammary gland as well as in practically all cases of mammary cancer, but he did not find them in epithelioma and sarcoma. He regards them as the morphologic results of the secretory activity of the glandular cells and holds that there is no cause for regarding them as parasites.

The mere enumeration of the principal conclusions of these investigations shows that the present cancer parasite theory in whatever form it may be stated does not receive any trace of support. The Boston investigators reach conclusions that are diametrically opposed to those of the Buffalo investigators as formulated by Gaylord and Rosewell Park in publications of recent date. The history of medical science shows that frequently the development of knowledge is greatly furthered by diversity of opinion and controversy among investigators. We hope that the different conclusions of these two sets of investigators now engaged in the study of the nature of cancer may have this desirable result.

#### THE MEDICAL POLICE POWERS OF THE STATE.

In a recent issue a legal publication<sup>1</sup> takes up the question of the right of the state to compel citizens to undergo medical treatment in case of sickness in order to prevent their wilfully sacrificing their own lives or endangering those of others. It admits that the state can interfere for a child whose parents do not supply due medical care and whose welfare is thus compromised, but says that no court has as yet to its knowledge ruled on the question whether or not it can thus act for an adult. It is not a question of suicide, for, as it says, the Dowieite or Eddyite has no desire to die but does not believe in medical treatment, and the right of the state to prevent him seems to be in doubt in the legal mind. The fact that there are different schools of treatment legally recognized complicates the question; Eddyism, Dowieism, etc., have all a like standing with regular medicine in the estimation of many lawyers and judges. Shall the state dictate how the citizen shall save his life is what they ask: the question is apparently a puzzler to them and common law and statutes are apparently both lacking for its solution.

1. Journal of Medical Research, No. 3, vol. vii.

1. Chicago Law Register, April 9.

When, however, the case is one of contagious disease or such as in any way may imperil the community, law does seem to come to the aid of common sense to a certain extent. In the matter of compulsory vaccination it appears there is at least one decision recognizing it as appertaining to the police powers of the state. Against this, however, there are other decisions that violate both consistency and common sense as well as the principles of medical science. The legal writer in the *Law Register* does not seem to believe in compulsory vaccination and disagrees apparently with the Georgia decision above referred to. He says "to make a failure to get vaccinated a criminal matter requires an exercise of arbitrary power more dangerous to the state itself in the long run than to the individual upon whom it is first visited." He holds, nevertheless, that the closing of schools to the unvaccinated children is a rather different matter; it is only the withholding of a privilege and not an invasion of a right. "A negative rather than a positive punishment is permissible where the injury apprehended is at best only speculative and problematic." If this is good law, what shall we say to the decision of a State Supreme Court that ruled that the exclusion of unvaccinated children was permissible only when an epidemic existed, thus locking the door after the horse had had a good chance to be stolen. To a medical man it appears that the police power of the state is exercised in many unequivocal ways no more evidently necessary than compulsory vaccination. The right to bear arms is guaranteed in the Constitution, but a man is subject to fine and confiscation of his weapon if he carries a pistol in his pocket. It does no harm there, the possible danger is purely anticipatory, but it is more easily realized by the average man than is that from non-vaccination. The legal principle, however, is or ought to be the same in each case.

We can not pose as law critics, but, if we had to accept the definition given of law as the culmination of human wisdom, we would often have to think poorly of the latter. We go as far as anyone ought, we think, in our regard for personal liberty and are willing to admit, if it is so required, that any mature individual of average sanity who wishes to undergo Eddyite or Dowieite or any other treatment should be allowed to do so and take the consequences, provided that in so doing he imperils no one else. With the modern developments of our knowledge of disease, however, the range of possible danger from communicable disease is shown to be vastly greater than was formerly believed, hence the need of all the more precautions for the public safety. No man liveth or dieth to himself and the world is beginning to realize this fact more than ever with the modern germ theories of disease. Just how far the police powers of the state will go in the near future it is impossible to say, but there seems every probability that they will receive a wider interpretation by the courts than has been given them heretofore. The state has its duty to the public it represents, not only to check existing disease by measures

within its power, but also to prevent it by any means which genuine science and experience have shown to be effective.

It is a noteworthy fact that, with a few insignificant exceptions, the active opposition to vaccination and other wholesome sanitary measures is led by quacks and off-color practitioners and their dupes—individuals whose occupation, under the salutary regulations now in force over the greater part of this country, is a direct active violation of the laws. It has come to be generally recognized that whoever undertakes to treat illness shall possess certain reasonable qualifications and statutes have been enacted to that end. It is chiefly the opponents and violators of such laws whose plea of injury to personal liberty and individual rights seems to have the respect of the legal editorial writer quoted above.

From his utterances and the Supreme Court decision referred to we are in some confusion as to what is good law in regard to the matter, but there is no doubt as to what is good common sense.

---

#### REORGANIZATION OF STATE SOCIETIES.

Probably few of our readers are aware that in nearly every part of the United States the movement for a better and more systematic organization of the medical profession is in progress. While some know that this movement is going on in their own locality or state, they can not very well know what is transpiring elsewhere, unless they are especially interested.

The officers of state societies, in many instances, have been stimulated to active work by the action taken and recommendations made by the American Medical Association at its last meeting, but there has been another potent and widespread influence—as some one expresses it, "organization is in the air." The large majority of the state bodies held their annual sessions during April and May, hence before the St. Paul session of the American Medical Association and consequently its action last June could not have been brought before them for action. Nevertheless, certain of the state societies, knowing that some action would probably be taken at St. Paul, appointed committees on reorganization last year, making it possible for some definite action to be taken this year. It is extremely gratifying to notice that of the two state societies which can take action this year, and which have already held their annual session—Tennessee and California—each has adopted a new constitution and reorganized in accordance with the recommendations of the national association. As reported in our "Medical Societies" column last week, the former adopted, with only two or three minor changes, the constitution and by-laws for the state societies just prepared by the Committee on Organization of the American Medical Association. The California State Society adopted a new constitution prepared by its own committee, but which includes the fundamental principles recommended. . .

The example set by these two states is likely to be followed by many others during the next five or six weeks, in which case we may look for practical results in this excellent movement much sooner than the most optimistic had hoped for.

It must not be lost sight of at this time that, while the adoption of a definite, systematic and business-like plan of organization is the first and most important step in the great scheme of organization, it is not the only work to be done. It is like adopting the architect's plan for a complete building, the work of putting up the building must follow and this will require time and energy, and—money. In the past we have been working without a definite plan, and there has been nearly as much pulling down as building up.

#### HAY'S REACTION FOR BILIARY ACIDS—A CORRECTION.

In *THE JOURNAL* of March 23, 1901, page 820, appears an editorial abstract of the work of Frenkel and Cluzet on the reaction with sulphur for the presence of biliary acids in urine and other fluids. "When sublimed sulphur—flour, or flowers, of sulphur—is added to urine containing bile, the sulphur immediately falls to the bottom." This reaction they termed Haycraft's reaction for bile, this being the name mentioned in connection with the reaction in Langlois and de Varigny's physiology. But it appears that the actual author of the reaction is Matthew Hay, professor of legal medicine in Aberdeen, and in a recent note Frenkel<sup>1</sup> makes the necessary correction. Professor Hay in 1886 inserted a note, describing the reaction in the second English edition of Landois' physiology, translated by Stirling (page 381), but the test was not described in the journals. Consequently the sulphur reaction for biliary acids should be known as Hay's reaction, the name Haycraft having become attached to the test through some error.

#### ANNUAL EXHIBIT OF THE PATHOLOGICAL SOCIETY OF PHILADELPHIA.

The Pathological Society of Philadelphia last year inaugurated the custom of holding an annual exhibition meeting, designed to illustrate the progress of pathology and to bring before the members in an objective manner pathologic subjects of contemporary interest. The second exhibit was held Jan. 9, 1902, and was largely attended. A list of the subjects presented occupies fifteen pages of the *Proceedings of the Society* (March, 1902) being composed of nearly three hundred items. Exhibits were made by over twenty individuals connected with the various laboratories in and about Philadelphia and they included gross and microscopic specimens in human and comparative pathology, cultures and slides of some of the bacteria which are especially interesting at present, and a series of blood preparations from the Pepper Laboratory of Clinical Medicine. The value of such an exhibit is manifold. As an educational factor among the physicians of the city where it is held, it must be of no little utility, and the possible good which may

come from it to the body of medical students in a large medical center like Philadelphia should not be disregarded.

#### THE GREGORY TESTIMONIAL BANQUET.

Last week nearly one-third of the members of the medical profession of St. Louis gathered in a testimonial banquet to one of their number who had just completed fifty years as a medical teacher. Dr. Gregory, the recipient of this honor, is an ex-president of the American Medical Association and has received many positions of honor and responsibility from his fellows, showing that he has always been held in high esteem. This fact is what prompted his confrères to show their appreciation of the man. It was not because he had done some great deed, nor because he was a great surgeon or a great scientist, but because he had been honest, faithful, hard working and unselfish during all these years of professional work. In honoring Dr. Gregory, the profession of St. Louis honored itself. This spontaneous exhibition of fraternalism shows a spirit that is typical of the highest and noblest there is in humanity. Such unselfish, brotherly and professional good-fellowship as that which prompted and carried out this affair shows a professional good-feeling that is always to be found among physicians whenever there is an opportunity to display it, although one can hardly believe it, judging from what one often sees on the surface. If there only were more of such gatherings among us they would help to do away with the petty jealousies and misunderstandings that are so liable to develop among medical men. We may not have too many meetings for scientific and educational purposes, but we certainly have too few social functions. Let us have more of them, even though we have to adopt some other excuse for them than to wait for some one to have taught or worked for fifty years.

#### RAILWAY EMERGENCY SUPPLIES.

One of the leading railroads in the middle west has initiated a practice that seems eminently proper and likely to be useful. Every freight and passenger train is supplied with an emergency medicine chest and packets and the trainmen are to be instructed in their use. It often happens that medical aid is not immediately available in cases of railroad accidents and if physicians happen to be present they are not always provided with the medicines and appliances that are desirable; hence the utility of first-aid packages and a supply of such drugs, etc., as are useful in cases of accident. The medicine chests for the passenger trains are naturally to be more complete and will contain a considerable variety of articles suitable for emergencies of sudden injury or sickness. On the freight trains the outfits are simpler and are accompanied with directions for their use. It is prescribed that whenever any of these packages have been opened or used that they be returned to the proper designated medical official of the road with a full account of the occasion of their use. Anyone who has had much railroad experience can recall cases where such provisions would have been most valuable for relief of suffering if not indeed for saving life. It is to be hoped that the example will be gen-

<sup>1</sup> *Jour. de Phys. et Path. gén.*, 1902, March 15, vol. iv, pp. 308-309.

erally followed by transportation companies. On many of our inland and coast steamboat lines similar provisions would be of the greatest value and are altogether neglected at the present time. First-aid packages for injury should at least be provided on every passenger train and boat. This should be a legal requirement, the enforcement of which should be a regular part of the duties of the steamboat inspection and whatever corresponds to this on land. In one or two of the countries of northern Europe this is the rule and the example should be followed everywhere. The public, of course, does not like to be reminded of the possibility of the dangers of travel, and such provisions would hardly be included in the advertisements of a transportation company, but a general knowledge that it provided for them would not hurt it any in general estimation, but on the other hand would, we believe, advance its reputation and popularity with the traveling public.

#### GYNECOLOGY FOR THE INSANE.

The extremely favorable results claimed by A. T. Hobbs<sup>1</sup> from his practice of gynecologic surgery among the insane again brings up this oft-discussed subject. A series of 253 cases operated on is reported, extending over a period of six years, during which 1000 female patients were received at the hospital. As a result of these operations 101 women are reported to have been restored to mental health and the annual discharge rate of the women's side of the hospital advanced from 37 per cent. to 52 per cent. The discharge rate for men, 35 per cent., during this time has remained the same. With the exception of this introduction of gynecologic surgery the treatment for the insane under Hobb's observation has remained practically unchanged for a long period. Hobbs makes some detailed analyses of his operative work and its results upon different forms of insanity, but certainly with too little discrimination between *post hoc* and *propter hoc*—a discrimination that is peculiarly necessary in drawing warrantable conclusions from any treatment of insanity. The value to the state as well as to the individual of a recovery from insanity makes the trial of any promising method of treatment a matter of sociologic import, but there is another reason for taking a moderately favorable view of remedying pathologic conditions in the insane. It is recognized that individuals mentally deranged have sufficient capacity for realizing the pains and pleasures of life so that the same physical conditions which cause suffering in those of sound mind very generally cause suffering, though perhaps not definitely recognized nor localized by the patient, to these unfortunates. So far as pelvic lesions are concerned, they may or may not be the particular bit of stress which carries an unstable nervous organization over the border-line between sanity and lunacy; according to Hobb's figures they often are, yet whether they are or not the treatment of such lesions may be of considerable benefit to the patient. Even the least result attained in suitable cases must be some comfort gained for individuals whose external conditions are hard enough to endure without at the same time being obliged to suffer from remediable organic ailments.

1. Amer. Journal of Obstetrics, February, 1902.

Certainty of improving the physical condition, probability of the improvement being reflected in better mental feeling and better behavior in some cases, added to the possibility of curing the psychical disease in a few, would seem to be inducement enough to warrant the introduction of properly controlled, competent, conservative gynecologic surgery in every hospital for the insane.

#### THERAPEUTIC VALUE OF THE CACODYLATES.

In a former issue of THE JOURNAL we suggested that the very favorable testimonials as to the value of cacodylic medication within the past year or so, ought not to be too implicitly accepted, but that they indicated that it deserved a judicial study.<sup>1</sup> These numerous testimonials as to its good effects hardly indicate in themselves such a study; they are generally *ex parte* observations, uncritical so far as any comparative trial with other forms of arsenical medication or chemical tests as to the actual efficiency of the basic drug. Dr. Thomas R. Fraser<sup>2</sup> in a paper read before the Edinburgh Medico-Chirurgical Society, March 5, reported some therapeutic tests by him of the cacodylate of soda which do not support the highly favorable reports of Gautier and others of its therapeutic efficacy. He tested it in cases of chorea, eczema, leukemia, and chlorosis, and found it practically ineffective as compared with other remedies. The cacodylate of iron was efficacious in chlorosis but this he holds was the effect of the iron alone. Three samples of urine were examined: one, as a control, to which liquor arsenicalis was added; one with cacodylate of soda oxidized in a special manner with mineral acids, and one with the cacodylate alone. Only the first two reacted to Marsh's test; the third showed no traces of arsenic. Fraser maintains that in cacodylates the arsenic is so thoroughly locked up with the methyl groups that to liberate it, prolonged oxidation with the mineral acids is required, and that therefore it can not be effective in the organism. The urine of patients being treated with cacodylate gave no arsenic reaction until after oxidation, when it was very marked. Fraser concludes from these facts that the arsenic in the cacodylates passes unchanged through the body. The action is analogous to that of cyanogen, which, while active in many of its preparations, enters into such stable combination in the ferro- and ferri-cyanids as to be entirely inert. The cacodylates, however, have their disadvantages; they irritate the gastro-intestinal tract, even when administered subcutaneously, and their long-continued administration is thereby seriously embarrassed. Fraser's results appear to have borne out completely his anticipations, as he says his investigation was prompted by his preconceived opinion of the inertness of these combinations. This fact may be utilized by the advocates of the cacodylic medication as affecting the value of his conclusions. Nevertheless, till they can be shown to be erroneous they cast a cloud upon the therapeutic value of these drugs.

1. THE JOURNAL A. M. A., Aug. 17, p. 455.

2. Medical Press and Circular, March 12, 1902.

MEDICAL JOURNALISM IN JAPAN.—We must realize that Japan is becoming one of the nations of the world. There are over thirty medical periodicals published in that country.

## Medical News.

### COLORADO.

**March Mortality.**—The State Board of Health report for March shows 783 deaths, an annual death rate of 15.78. Diphtheria caused 39 deaths; scarlet fever, 28; typhoid fever, 7, and smallpox 1.

**Home for Needy Consumptives.**—Charles L. Adams of Pittsburg, Pa., has given \$30,000 for the erection of a home for indigent consumptives in Denver, and has promised to give \$20,000 in addition conditional on the securing of a like amount.

**Board of Health Sustained.**—According to a decision just rendered by Judge Voorhees, a board of health, whether it be a state, county or city board, has absolute power to make rules and regulations governing the sanitary conditions of a community. This decision was given in denying an application made for an injunction to restrain the mayor and school board of Rocky Ford from preventing a child from attending school because she had not been vaccinated.

**Instructions to Health Officers.**—The State Board of Health has made the following suggestions to health officers:

In case of death from cancer, require a statement of the organ or organs involved in the process, or a statement as to whether the process was general.

In case of death from septicemia, peritonitis or hemorrhage in an adult female, require a statement as to whether it was puerperal in character.

In case of death from inanition, marasmus, mal-nutrition or dropsy, secure, if possible, a definite statement of cause.

In case of death from violence or poison, have the death certificate state whether it was suicide, accident or homicide.

In case of death from tonsillitis, spasmodic croup, or other suspicious disease of the throat, investigate as to the question of diphtheria, and require the certificate to show the facts.

Do not accept the statement of "heart failure" as a cause of death.

Death certificates are required for still births and premature births, provided the fetus is twenty-eight weeks old. In all such cases, be sure to see that the death certificate states whether the child lived.

### DISTRICT OF COLUMBIA.

**American Gastro-Enterological Association.**—The fifth annual meeting of this Association will be held in Washington, May 1, under the presidency of Dr. John C. Hemmeter, Baltimore. A luncheon is to be given to the members by Dr. William Gerry Morgan.

**In Memory of Dr. Johnston.**—A public meeting was held, April 9, by the Medical Society of the District of Columbia, in memory of the late Dr. William Waring Johnston. Resolutions were adopted providing that a memorial pamphlet be published embodying the addresses made, an embossed copy of which shall be forwarded to the bereaved family.

**Proposed School Inspection.**—The Medical Society of the District of Columbia recommends the system of medical inspection of public schools outlined by the Commissioners. This inspection should be under the health officer and inspectors should be appointed after competitive examination. Pupils in the normal school should be taught to recognize the earliest manifestations of communicable disease, so that they can intelligibly co-operate with the inspectors.

### ILLINOIS.

**Fire Loss.**—Dr. Ralph P. Dowd suffered a loss of about \$1000, with no insurance, by the recent fire at Fisher.

**Doctor Robbed.**—A burglar at Springfield not only robbed the residence of Dr. Percy L. Taylor, April 15, but also forced the doctor and his wife to accompany him while he was securing such valuables as he desired.

### Chicago.

**Ex-Internes Feast.**—The ex-internes of Cook County Hospital were the guests of Warden Healy, April 19. Dr. William E. Quine acted as toastmaster and toasts were responded to by Drs. John B. Murphy, James B. Herriek, Robert Bruce Preble, C. E. Kahlke, and John D. Robertson.

**National Association of Trained Nurses.**—This Association will meet at the Lexington Hotel during the first week in May. The management of Mercy Hospital and the Mercy Hospital Alumna Association of Trained Nurses have arranged a clinic to be given for the associations at the hospital by Drs. John B. Murphy, Arthur R. Edwards and others at 10 a. m., May 1.

**Dunning Rules Revised.**—At a meeting of the special Dunning committee it was decided to formulate new rules to govern the County Hospital for the Insane and the Poor Farm.

The appointment of a medical director, head nurse and a business manager make this necessary. Drs. Frank Billings and Hugh T. Patrick, Julia Lathrop, President J. J. Hanberg, Commissioner W. K. Walker and J. E. Flannigan were appointed a committee for this purpose.

**The Officer-of-the-Day Again.**—The officers-of-the-day at the County Hospital have recommended: 1. That church services be held in the amphitheater. 2. That a ward be assigned for sick house physicians and attending physicians. 3. That an annual report be issued of the number of cases treated, the deaths, general information concerning the hospital and all data which would be of interest to the medical profession. 4. That the rule prohibiting profanity be strictly enforced.

**New Hospitals.**—The trustees of the Frances E. Willard Hospital are considering a proposition to acquire additional east frontage in Lincoln street, north of Harrison street, and to erect a hospital building to cost about \$250,000. Bequests have been made for about \$21,500, which leaves a little more than \$228,000 to be raised.—Maimonides Hospital Association has been incorporated by Dr. Gustavus M. Blech and others.—Watts De Peyster Hospital and Home for Invalid Children has been incorporated.—Plans are being prepared for a six-story addition to Augustana Hospital to cost about \$100,000.—Protests have been received by the building department of the city against the erection of hospital buildings by the Chicago Polyclinic at Oak Street and La Salle Avenue, and by Dr. Nathan E. Wood, at 617 La Salle Avenue.

### INDIANA.

**Central College of Physicians and Surgeons, Indianapolis,** graduated a class of 8 at its twenty-third annual commencement exercises, April 17.

**Banquet for Dr. Ferris.**—The professional friends of Dr. Edgar S. Ferris, New Castle, who is about to leave for the east for a year of special study, tendered him a banquet, April 8.

**St. Edward's Hospital, New Albany,** recently erected at a cost of \$90,000, was dedicated, April 8, with appropriate ceremonies. The hospital will be in charge of the Sisters of St. Francis.

**Fined for Violation of Law.**—Dr. Louis Lukenbill, Marco, was fined \$10 and costs, April 14, for interfering with quarantine regulations in Vigo township, Green County.—Gideon Stevens, living near Stroh, La Grange County, plead guilty to the charge of practicing medicine without a license, and was fined \$25 and costs.

**Death and Disease.**—The monthly report of the State Board of Health shows that there were 3045 deaths in March, the annual rate per 1000 being 14.2. In the corresponding month last year the number of deaths was 3272, the rate 15.3. Compared with the preceding month, there were 171 more deaths. Of this increase, 88 or almost 50 per cent. was of children under 15 years of age and 20 per cent. was of people over 65 years. Diseases which caused the increase in the number of deaths in March over February, were consumption, measles and puerperal fever. The deaths from important causes were: tuberculosis 457, typhoid fever 39, diphtheria 26, scarlet fever 18, measles 22, whooping cough 16, pneumonia 470, diarrheal diseases 9, cerebrospinal meningitis 21, influenza 59, puerperal fever 21, cancer 82, violence 127, smallpox 2. From influenza alone was the death rate higher in the country than in the cities, the rates per 100,000 being: cities, 26.1; country, 28.4. The violence death rates in 100,000 were: cities, 94.9; country, 41.2. Aside from smallpox the prevalence of diseases was in the following order: Rheumatism, bronchitis, influenza, pneumonia, tonsillitis, measles, intermittent fever, pleuritis, diarrhea, scarlet fever, erysipelas, typhoid fever, diphtheria, cerebrospinal meningitis, whooping cough, inflammation of bowels, puerperal fever, cholera morbus, dysentery and cholera infantum.

### IOWA.

**Keokuk College of Physicians and Surgeons** held its commencement exercises, April 14, graduating a class of 64. On April 15 the alumni held their annual banquet, over which Dr. George F. Neff, Farmington, presided as toastmaster.

**Hospitals.**—Articles of incorporation of the Benjamin Hershey Memorial Hospital, Muscatine, have been filed.—The new detention hospital at Des Moines, erected at a cost of \$13,000, is now ready.—Clark Hospital, McGregor, will be ready to receive patients, May 1.

**Made Surgeon-General.**—Dr. Henry Munson Dean, Muscatine, major and surgeon-general of the Department Command

of Iowa, Union Veterans' Union, has been appointed surgeon-general on the staff of the commander-in-chief, national command, of the organization, with the rank of colonel.

### MARYLAND.

**The Frederick City Hospital** was formally opened on April 22. The state gave \$5000 toward its erection and \$3500 for two years for its maintenance.

**The Medical and Chirurgical Faculty of Maryland** held its annual meeting, April 22, 23 and 24. Dr. James Tyson, of Philadelphia, delivered the oration.

**The Baltimore University School of Medicine** held its annual commencement, April 15. Rev. Dr. Donald Guthrie delivered the oration, and Dr. E. Miller Reid conferred degrees on 31 graduates. A dental department is said to be in contemplation.

**Alumni Association of the College of Physicians and Surgeons of Baltimore.**—The annual meeting of this body will be held, April 28, at Baltimore. Dr. Samuel H. Allen, Provo City, Utah, will be the orator. The meeting will be followed by a banquet at the Hotel Rennert.

**Medical Librarians' Bulletin.**—The first number of the *Bulletin of the Association of Medical Librarians*, appeared in Baltimore, April 19. It contains "A Visit to the Hunterian Library at Glasgow," by Dr. William Osler, and "The Library of a Colonial Physician," by Dr. Cordell.

**Personal.**—Dr. Edward N. Brush, of the Sheppard and Enoch Pratt Asylum, sailed for Europe, April 23.—Dr. E. G. Ballenger, of the University Hospital, has been appointed surgeon of the Maryland Granite Company, and will reside at the quarries, Guilford, Howard County.—Dr. P. E. Stigers was appointed a pension examining physician at Hancock.

**Lectures.**—Dr. William Osler gave a lecture, illustrated by lantern pictures, before the Medical and Chirurgical Faculty, April 22, on "The Diagnosis of Smallpox."—Prof. J. Gaule, of the University of Zurich, Switzerland, lectured at Johns Hopkins Hospital, April 21, on "The Effects of Changes in Altitude Upon the Blood Corpuscles," with demonstrations of preparations.

**Lazear Memorial.**—The committee of the Medical School of the Johns Hopkins University, appointed to erect a memorial to the late Dr. Jesse William Lazear, who lost his life as the result of an experiment on the transmission of yellow fever, reports that sufficient money has been subscribed to erect a memorial tablet and to establish a library fund for the purchase of works relating to tropical diseases.

### MICHIGAN.

**No Quorum.**—At the annual meeting of the State Board of Health, April 11, a quorum not being present, much important business waiting for this meeting could not be transacted. The members present had a long conference on important subjects, and conducted the examination in Representative Hall of 45 embalmers who were applicants for license.

**Appeals to Supreme Court.**—Peter Radebaugh, who represents that, upon the assurances of a member of the State Board of Medical Examiners, he located at Sturgis, intending to engage in the practice of medicine, has applied to the Supreme Court for a mandamus to compel the board to recognize the Miami Medical College of Cincinnati as a reputable college and to issue him a certificate entitling him to practice. He claims that the board is discriminating between reputable colleges.

**Emergency Hospital Opens.**—The building given to Grand Rapids by Dr. Louis Barth for an emergency hospital opened April 8. The hospital is supported by the sale of certificates, the holders of which are entitled to medical aid and a free bed in case of accident so long as needed. The annual fee for a certificate is \$2, and should husband and wife in one family each hold tickets all children under 15 years of age are entitled to free service. Drs. L. A. Cottle and L. B. Hayden, of Boston, are in charge. No contagious diseases will be treated in the new hospital as planned at present, but all accidents and surgical cases will be received.

**Mortality of Michigan.**—There were 2959 deaths reported to the Department of State for the month of March, corresponding to an annual death rate of 14.1 per 1000, a slight increase over the rate for February, which was 14 per 1000. There were 495 deaths of infants under 1 year of age; 205 deaths of children aged 1 to 4 years, inclusive, and 912 deaths of elderly persons over 65 years. Important causes of death were as follows: Pulmonary tuberculosis, 200; other forms of tuberculosis,

21; typhoid fever, 41; diphtheria and croup, 33; scarlet fever, 37; measles, 34; whooping cough, 29; pneumonia, 385; influenza, 70; cancer, 119; accidents and violence, 147. The most marked features of the month were the increased numbers of deaths from pulmonary tuberculosis and the common diseases of children, scarlet fever, measles and whooping cough.

### MISSOURI.

**St. Louis College of Physicians and Surgeons** held its commencement exercises, April 7. A class of 50 received diplomas.

**Testimonial to Dr. Gregory.**—A testimonial banquet was tendered Dr. E. H. Gregory by the profession of St. Louis, April 17, a fuller notice of which will appear in our next issue.

**Barnes Medical College, St. Louis**, graduated a class of 79, three of whom were women, April 10. Rev. John D. Vineil, chairman of the board of trustees, delivered an address; Dr. Meredith D. Jones was faculty valedictorian, and Dr. Abram M. Carpenter presented the faculty prize medals.

### NEW YORK.

**Personal.**—Dr. Carl G. Leo Wolf was appointed health officer of Niagara Falls.—Dr. A. L. Chapen has been appointed police surgeon and Drs. F. Guillemont and W. P. Russell physicians to the poor at Niagara Falls.

**Bars Patent Medicine Distribution.**—The Oswego Department of Health, at its meeting, April 10, passed a resolution that no person be allowed to distribute patent medicine without permission of the Board of Health, and, further, that the chief of police be directed to carry out the order.

**Cause of Diphtheria Infection.**—Dean Estewen A. Fuertes, of the College of Civil Engineering, Dr. George A. Caldwell, and Dr. Veranus A. Moore, all professors in Cornell University, who were appointed by the State Lunacy Commission to investigate the cause of diphtheria which has been prevalent at the Willard Insane Asylum for some years, have found that the ventilation was imperfect, that germs of diphtheria were taken up to the garret by upward currents of air, and then either by changes in the direction of the wind or by the opening of windows in the lower floors these germs were distributed again through the building.

### New York City.

**Bequest to a Hospital.**—By the will of the late William Whitewright, a well-known bachelor of this city, \$50,000 is left to the Presbyterian Hospital.

**Brokers to Endow Hospital Bed.**—A movement is on foot in the Stock Exchange to endow a hospital bed in order to meet the frequent demands made upon the members for assistance for sick and disabled employees.

**Dr. Alvah H. Doty**, Health Officer of the Port of New York, has received from the directors of the Pan-American Exposition at Buffalo a gold medal for his exhibit on sanitation which consisted of models of boats, quarantine plant, islands, with photographs and other material.

**New Hospital for the Bronx.**—Governor Odell, on April 14, signed the bill authorizing the construction of a new hospital in the Borough of the Bronx. It directs the Sinking Fund Commission of the city to have bonds issued for \$200,000 to be used in acquiring the site for the proposed structure and for \$300,000 for erecting and equipping the building.

**Mortality of Greater New York.**—The report of Registrar Guilfoyle to Commissioner Lederle, of the Board of Health, for the first quarter of the present year, shows 18,364 deaths, as compared with 18,575 deaths for the first quarter of 1901. This is a rate of 20.22 per thousand, as against 21.01 per thousand for last year. There was a decrease of 282 deaths from consumption, an indication that the measures instigated by the Department are bearing fruit.

**The City Tuberculosis Hospital.**—The hospital for persons having pulmonary tuberculosis, started by the city authorities on Blackwell's Island last February as an experiment, is reported to be doing good work. In all, 273 patients have been received, about fifty of whom were practically in the very last stage of the disease. About an equal number had the disease in an advanced form. There have been 76 deaths, while 50 patients have been discharged greatly improved. There are now 114 patients, forty of whom are in the later stages.

**More than a Million Needed for Isolation Hospitals.**—President Lederle of the Board of Health has transmitted his estimate of the amount required by his department for repairs, alterations and new buildings for the contagious disease hos-

pital service of the five boroughs. For the Borough of Manhattan, \$600,000 is required; for Borough of the Bronx, \$100,000; for Borough of Brooklyn, \$125,000; for Borough of Queens, \$100,000; for Borough of Richmond, \$50,000, and for North Brother Island, \$50,000—in all, \$1,025,000 is needed.

**Unlicensed "Nature Curer."**—"Doctor" August F. Reinhold, the proprietor of a "Nature Cure" sanitarium, has been brought into unpleasant notoriety by the death in his establishment of a fourteen-year-old girl, temporarily boarding there. Though the autopsy ordered by the coroner declared that death had resulted from valvular disease of the heart and pulmonary edema, it is thought that the cold baths given her by Reinhold when she became ill hastened her death. Although it is said that Reinhold circulates literature, bearing his name as author, and having appended the titles Ph.D. and M.D., Reinhold admits that he is not a registered physician.

**New Entrance Requirements.**—The plan for advancing the standard of requirements for entrance to the College of Physicians and Surgeons has been completed and has received the approval of the University Council. Heretofore any one who had a Regents' forty-eight-count medical student's certificate could enter the first-year class in the college. A student who has only thirty-six counts may enter, but must make up the remaining twelve before the close of one year. The new plan provides that after July 1, 1902, no student who does not have the full forty-eight counts will be admitted. The most important provision of the new plan will go into effect July 1, 1903. By its terms no student will be admitted to the school who has not secured his certificate in one of these two ways: 1. By having successfully completed one full year's course in a college or scientific school of the United States, or an equivalent course in a European institution. 2. By passing an entrance examination conducted in June of any year by the College Entrance Examination Board, or in September by Columbia University.

#### Buffalo.

**Personal.**—Dr. Roswell Park will deliver the address at the anniversary exercises at Yale Medical School, June 24.—Dr. Charles G. Stockton has returned from a trip to the Orient.—Dr. Charles Cary is visiting in the East.—Dr. Edward J. Meyer, who was obliged to go to Florida for his health a few weeks ago, has returned, greatly benefited by the change and rest.

**Ventilation of Schools.**—There has been much just criticism concerning the ventilation of Buffalo schools, especially those of most recent construction. In these buildings recently erected the city has expended large sums for a ventilation system installed by a local firm, and after examination it is now found that the system is not efficient, so that in the construction of the new West Side High School, Professor Woodbridge, an expert from Boston, has made plans for a far less expensive and more efficient ventilation system.

**Infection by Barbers.**—The health ordinances for the prevention of the spread of disease through the medium of barbers' razors and other appurtenances to the trade in barber shops is to be rigidly enforced. The ordinance requires that the razor shall be sterilized before it is used on each customer, compels the barber to provide a fresh clean towel for each customer and prohibits the use of alum in such form that the same alum comes in contact with more than one face. The barbers are also required to wash their hands before shaving each customer.

#### PENNSYLVANIA.

**Memorial to Dr. Onstott.**—The McKee's Rocks Medical Society held a special meeting, April 5, at which resolutions of sorrow and sympathy regarding the death of Dr. J. W. Onstott were unanimously adopted.

**Damage Suit Settled.**—The suit for \$50,000 damages, brought by Andrew J. Miller against Dr. Samuel L. McCarthy, Altoona, for malpractice, whereby it was alleged that plaintiff lost his right arm, has been settled by mutual agreement.

**Personal.**—Dr. H. B. Lockhead has been added to the house staff of Pittston Hospital.—Passed Assistant-Surgeon Raymond Spear, U. S. N., of Norristown, has received the thanks of the Colombian government for valuable services rendered to wounded Colombian soldiers during the recent revolution.

**Bryn Mawr Hospital Enlarged.**—The Garrett Memorial wing of Bryn Mawr Hospital was opened to-day with appropriate ceremonies. The capacity of the hospital is doubled by this addition. The Garrett memorial wing was erected to the memory of William E. Garrett, Jr., who, before his death, gave to the hospital the operating room. It contains twelve rooms

and has been furnished by the donors at a cost of \$10,000. The wing is for private patients only.

#### Philadelphia.

**Dinner to Dr. Turner.**—On the evening of April 13 Dr. Charles K. Mills gave a dinner, at the University Club, in honor of Dr. William Alden Turner, of London, the well-known neurologist, and of his brother, Dr. Logan Turner, the laryngologist. The distinguished guests are sons of Sir William Turner of London.

**Sanatorium for Incipient Tuberculosis.**—The trustees of the Rush Hospital for Tuberculosis have recently bought, for a country branch, a farm of 47 acres in Chester County. The land is elevated, and is thought to be favorably situated for the treatment of incipient cases. If the treatment proves successful cottages will be erected.

**Personal.**—Dr. William M. Thompson recently sailed from New York for London. He will visit many of the hospitals abroad.—Dr. John B. Deaver, accompanied by Drs. A. E. Wilcox and G. G. Ross, resident physicians of the German Hospital, were passengers on the *Kronprinz Wilhelm*, for Bremen, April 8. The party will be abroad about two months, visiting Halberstadt, Heidelberg, Paris and London.

**Bequests.**—By the will of Mrs. Mary A. Allison \$5000 is left to the Methodist Episcopal Hospital, and \$2500 to the Presbyterian Hospital.—The will of Owen Lamb, after bequeathing \$500 to each of several Catholic institutions, including St. Joseph's Hospital, devises his residuary estate, estimated at \$50,000, to the Sisters of St. Francis, for the support of St. Mary's Hospital and to the Society of St. Joseph, for the maintenance and education of poor orphan children.

**Death of Pioneer Masseuse.**—Jessie Miller Ward, the first in the country to teach massage upon a scientific basis, died April 6, at the Presbyterian Hospital. After two years of study at the Women's Medical College, ill health compelled Miss Ward to turn her energies in another direction. She attained distinction in this valuable branch of therapeutics. For some time she had been giving courses in massage at some dozen leading institutions of the city, and was the author of a valuable text-book on the subject.

**Municipal Hospital Management Endorsed.**—At a business meeting of the County Medical Society, April 16, which was largely attended, the constitution was revised, a number of new members were elected, and, on motion of Dr. E. E. Montgomery, the following resolutions were unanimously adopted: "Resolved, That the Philadelphia County Medical Society heartily endorses the administration of the Municipal Hospital of Philadelphia during the smallpox epidemic." "Resolved, That it commends Dr. William M. Welch and his able corps of assistants for the efficient and thorough manner in which every detail of the arduous and responsible work of that institution is, and has been, carried forward."

#### GENERAL.

**Leper Settlement Undermined.**—It is reported that the peninsula of the island of Molokai, Hawaii, on which the lepers live, is undermined by the sea for some distance. The lepers are alarmed and the superintendent will investigate.

**Nine Hundred Cholera Deaths.**—The total number of cases of cholera in the Philippine Islands up to April 20 was 1244, of whom 902 died. In Manila alone there were 388 cases and 300 deaths. The commission has passed laws authorizing municipalities to appropriate funds for the extermination of epidemic diseases.

#### Smallpox.

California: Stockton schools were closed, April 12, on account of the reappearance of smallpox.

Colorado: The State Board of Health has devoted considerable energy to tracing the source of infection of the 254 cases of smallpox reported during March. Their report shows that of these cases, 197 originated in the town or country from which each was reported, 41 came from other counties or adjoining territory, 7 had an origin that could not be ascertained, and 9 came from outside the state. Among the latter were 3 cases from Kansas, 2 from Missouri, and 1 each from Michigan, Wyoming, New Mexico and Nebraska.

Connecticut: The report of the State Board of Health announces that smallpox is still occurring sporadically in several towns, but is epidemic only in Waterbury. As an illustration of the possible control of the disease, it is reported that, except in Waterbury, it has been limited to one case in five other towns and to two cases in the other two towns in which it has

appeared. Its greater spread in Waterbury is due to the large number of unvaccinated persons, the large foreign population, and the greater facilities for concealing the presence of the disease until many have been exposed to it. The disease was reported during March as follows: Berlin, 1; East Windsor, 1; Putnam, 1; Southbury, 1; Stamford (city), 2; Thomaston, 1; Waterbury, 23; Windsor Locks, 2. Total, 32 in 8 towns.

Illinois: East Galesburg reports a new outbreak of the disease with three cases. The parents of the children affected are among those who do not believe the disease is smallpox.—Chicago: The Department of Health reports that smallpox, which has heretofore been very mild—only one death in 139 cases since January 1—is taking on the old-time typical form, with pronounced initial symptoms, profuse eruption and high secondary fever. Five out of the eleven cases discovered during the week, including one from Iowa and one from New Jersey, were of this type.

Indiana: Smallpox was the most prevalent disease in March, 785 cases being reported as follows: Jay County 12, Hendricks County 2, Union County 1, Porter 1, Montgomery 41, Howard 3, Noble 46, Cass 4, Carroll 1, Shelby 37, Lawrence 12, Dekalb 1, Wayne 2, Vermillion 1, Morgan 1, Martin 1, Dubois 20, Wabash 16, Delaware 17, Clay 19, Warrick 61, Madison 64, Whitley 4, Clark 5, Gibson 22, Owen 1, Wells 81, Tippecanoe 1, Floyd 2, Lagrange 16, Perry 10, Posey 2, Allen 13, Vigo 6, Daviess 29, Vanderburg 54, Franklin 40, Adams 55, Knox 44, Marion 64, Grant 20, Greene 5, Spencer 2, Henry 2, Miami 3, and Benton 1. The two deaths reported from smallpox during the month were one each in Montgomery and Shelby Counties.

Iowa: The legislature has enacted a law which empowers the board of supervisors to levy on each city or incorporated town the expense of the quarantines. The city or township in which a case of smallpox originates will have to bear the expense of quarantine. The county treasurer is protected by granting the board of supervisors discretionary power in regard to accepting contracts made by local boards of health. If the supervisors decide that a contract made by the local board of health in smallpox cases is not reasonable or just they can repeal it. The State Board of Health is given power to enforce quarantine and vaccination regulations and rules when local boards fail to do so. Police and peace officers in the state, when called upon by the State Board of Health to enforce such rules and regulations, must execute the orders of the board, and the expenses shall be paid by the local boards of health. Any person affected with smallpox may be removed to a separate house or contagion hospital, and if it is impossible to so remove such person he may be cared for at his home, the removal of affected persons to be made after an application has been made before a magistrate. The removal shall be made under the direction of the local board of health.

Maryland: There are several mild cases of smallpox in Caroline County.

Michigan: Smallpox was reported present at 157 places in the state during the week ended April 5. Three deaths occurred from smallpox during March, 1 in Escanaba City, 1 in Clio village, Genesee County, and 1 in Chesterfield township, Macomb County.

New York: At a recent meeting of the New York State Medical Association, Dr. S. Dana Hubbard, in discussing the increased prevalence of smallpox in the United States, made the following assertion: "In my opinion the country has been re-infected with smallpox from the Philippines in the last two or three years."

Ohio: Miamisburg is said to have 56 cases of smallpox; Seio has 8 cases; Laceyville one case, and 6 cases in the Fayette County Children's Home near Washington Court-House. A conference of the state boards of health of Ohio, Illinois, Kentucky, Michigan and Indiana for the discussion of means of checking the smallpox epidemic was held in Indianapolis on April 25.

Pennsylvania: Superintendent Geary, of the Philadelphia Hospital, has announced that the quarantine against visitors on account of smallpox, which has been maintained since last October, has at last been raised. It is thought that the danger from the disease has so far abated as to render such restriction unnecessary, not only at this hospital, but at others as well.

South Dakota: It is announced that 207 persons were vaccinated at the Green Front Theater in Deadwood, April 13. The place is a variety house and dance hall, and a case of smallpox was discovered there. Four doctors and the sheriff performed the operation. Five men who objected spent the night in jail. This action is in conformity with a recent order

of the Board of Health requiring all persons to be vaccinated, and it is to be extended to all public resorts where there are large numbers of people. The doctors have gone through the public schools and teachers and pupils were vaccinated.

Texas: The State Health Department has been advised of the existence of considerable smallpox at Beckville. State Health Officer Geo. R. Tabor left at once to investigate.

England: The smallpox epidemic in London continues. The deaths from the disease up to April 5 numbered 1015. They are classified according as the cases had been vaccinated, unvaccinated, or revaccinated. Of those who had been vaccinated 534 died, and 398 unvaccinated died. Of the 534 vaccinated cases 427 had been vaccinated in infancy, and only one of these was noted as having been imperfectly vaccinated. Under the age of 10, 414 were vaccinated and over that age there were 20. As against the claim that the efficacy of infant vaccination is spent, not one death of a person who has been revaccinated is recorded within the last ten years, in spite of the universal prophecy to the contrary.

## CANADA.

**New Chairs for Laval University, Quebec.**—To commemorate the jubilee of Laval University, Quebec, in June, old scholars will contribute to the establishment of several new professorships. Already over \$10,000 has been offered. Dr. A. G. Belleau, of Quebec, has given \$1000; Dr. Arthur Vallee and Dr. Rosseau \$500 each.

**Government Bacteriologic Station.**—For the past three years the Department of Agriculture has been maintaining a station at Outremont, near Montreal, where scientific observations have been made regarding tuberculosis in cattle. The minister has ordered the station to be closed and the bacteriologist in charge, Dr. Higgins, has been transferred to the cattle quarantine staff at Ottawa. These investigations will henceforth be conducted at Ottawa. It is likely that the researches will be extended to tuberculosis in human beings.

**Montreal Western Hospital.**—On Tuesday afternoon of last week the quarterly meeting of the board of governors of this institution was held. Dr. H. L. Reddy, one of the attending staff, resigned, and was subsequently appointed to the consulting staff. Dr. W. Grant Stewart was appointed to succeed him. The report of the committee of management was read by the secretary, Dr. Alex. Macdonald. During the first three months of the year there have been treated 43 medical cases, 58 surgical and 30 gynecologic cases, or a total of 131, as compared with 102 in the corresponding period of 1901.

**To Help Women Inebriates.**—The Local Council of Women at Ottawa have adopted a resolution asking that the government establish cottage homes for inebriate women. They state that in their city of Ottawa intemperance among women and girl prisoners has increased to the alarming extent of 75 per cent.; and that women in many cases under or about the age of 20 have been incarcerated for drunkenness or for crimes committed while under the influence of drink. Imprisonment to check this evil has proven an utter failure as there are women in a brief life of 40 years who have spent 20 years in jail.

**Laws Upon Sending Patients with Infectious Diseases to Hospital.**—At a meeting of the Montreal Hygienic Committee held last week, Alderman Ames brought up this question. He stated he had collected legal advice on the matter and the city attorney had stated that if a patient is residing in a hotel, boarding house or tenement containing more than one family, a vessel, railway car or carriage, the sanitary authorities are empowered to remove that patient and place him in a hospital, but this is not the case when a patient resides in a self-contained house. The Provincial Board of Health at Quebec will no doubt be asked to give the local board power by by-law to enforce the removal of smallpox patients.

**The annual convention of the Canadian Association for the Prevention of Tuberculosis** was held at Ottawa, April 17 and 18. Hereafter there will be a permanent central organization at Ottawa, and an efficient paid secretary will be appointed. There are said to be at the present time in Canada between 30,000 and 40,000 consumptives, the average number of deaths yearly totaling 9000, or one in every 650 of the population. It was recommended that the Federal and Provincial Governments should grant aid toward preventive measures and that measures should be taken to guard against the importation of immigrants suffering from tuberculosis. The following were the officers elected: President, Mr. W. C. Edwards, M.P.; secretary, Dr. H. B. Small, Ottawa.

**The Question of Diseased Immigrants.**—We referred last week to the warning of the United States immigration officials concerning those refused admittance to the United States. During last week this vexed question was up for discussion in the Canadian House of Commons, and it was denied that many of these are allowed to remain in Canada. The Minister of the Interior, under whose control is immigration, referred to the extravagant statements which had been circulated in this connection and illustrated by saying that an investigation had been made into the published statement that there were 200 diseased immigrants in the hospitals of Montreal. The report sent in by the superintendent of Notre Dame Hospital of that city showed that there were two cases in January, two in February and six in March. There had been none in the Royal Victoria Hospital for six months, or in the Montreal General for three months, and in the Hotel Dieu there were seven. Of 25,000 persons who came into Canada 132 were rejected by the United States commissioners as undesirable, and of these 132 there are now 29 in Canada.

**Personal.**—Dr. H. H. Sanderson, of Windsor, Ont., has gone to London, Eng., where he will take a special course in the hospitals. He will continue his studies in Berlin before returning. —Dr. David Shirres, of McGill University, has been appointed professor of nervous diseases at the University of Vermont. —Dr. Charles Sheard, Medical Health Officer, Toronto, and Dr. H. B. Anderson, editor of the *Canada Lancet*, have returned home after spending a holiday in New York. —Dr. Graef, of Vancouver, is attending the New York Post-Graduate Hospital, doing special work on the eye and ear. He will shortly leave for England to further prosecute these studies. —Dr. T. H. Morgan, Trinity '97, has been appointed an assistant in Dermatology at the New York Post-Graduate Medical School. —Dr. A. E. Randall, of Truro, N. S., is collecting a Muir memorial hospital fund in memory of the late Dr. Muir. —It has been lately currently reported that Colonel Neilson, director-general of the Army Medical Service of Canada, was to resign to be succeeded by Dr. Fiset, of Quebec. This has received official denial, Dr. Neilson having been granted leave of absence for a few months, Dr. Fiset acting temporarily.

#### FOREIGN.

**The American Hospital in Mexico City** treated 61 patients in March and discharged 33. Three died and 4 operations were performed.

**French Must Vaccinate.**—Vaccination is now obligatory in France within the first year from birth, and must be followed by revaccination at the ages of 11 and 21.

**Prophylaxis of Tuberculosis.**—The German central committee has ordered 150,000 copies of its pamphlet on tuberculosis to be distributed in the public schools.

**Germans Buy Goats.**—Tuberclephobia in Germany is causing the importation from Switzerland of many goats to replace cows as a milk supply, since goats seem so rarely susceptible to tuberculosis.

**Argentine Plague Mild.**—There is no alarm over the outbreak of plague at Buenos Ayres, Argentine, the cases are few and not severe, and the president of the sanitary department does not apprehend a spread of the disease.

**Abolition of Compulsory Vaccination.**—By a recent act of Parliament, vaccination is not compulsory in South Australia for a person (or the parent of a child) who makes a sworn declaration to his belief that vaccination would be prejudicial to health.

**Russian Supervision Over Advertisements.**—A certain widely-advertised disinfectant for the mouth has proved to be without antiseptic properties, according to the Russian authorities, and consequently papers are prohibited from accepting its advertisement except with the sole claim that it is a cosmetic for cleansing the mouth.

**Many Lepers in Nicaragua.**—The newspapers of Nicaragua are warning the people against the danger from leprosy. They say that fifteen years ago there were about 200 lepers in the country and now there are nearly 2000. These are allowed to go about anywhere and beg, and the papers declare the disease is spread by incidental contact.

**Gift to Aberdeen Infirmary.**—The Royal Infirmary at Aberdeen, Scotland, has received a gift of \$150,000 from Lord Stephen, who had previously paid a debt of \$125,000 which was hanging over that institution. Lord Stephen was formerly president of the Canadian Pacific Railroad and the famous mountain peak of the Canadian Alps is named after him.

**Mexican Tuberculosis.**—According to *El Imparcial*, Dr. Eduardo Liceaga has published a complete record of statistics of mortality caused by tuberculosis in the City of Mexico, during the 32 years from 1869 to 1900. The deaths in 1869 were 7447, and in 1900, 19,272. Mortality has nearly tripled therefore. Deaths in the last decade are almost double the number in the first decade.

**New Chinese Hospital.**—On December 7 the Elizabeth Shilton Danforth Hospital was opened at Kiukiang, under the Methodist Central China Mission. The two physicians, Drs. Stone and Kahn, had 7854 out-patients in the preceding twelve months. Their new facilities include a glass operating room, and modern equipment for distilling, sterilizing and microscopic work. The English and American consuls made addresses.

**Deaths Abroad.**—Dr. M. Piza, of Hamburg, one of the most prominent and devoted members of the executive committee of the national Aerztevereinsbund, has died. —The death of the Russian psychiatrist, Professor I. Balinski, is also reported from St. Petersburg, and of Crouzat, professor of obstetrics at Toulouse. —Professor R. N. Bruzelius died recently at Stockholm in his 71st year. His tastes inclined him most to laryngology and zoology, but he was physician-in-chief at the Serafimer Hospital.

**Death of Hans Buchner.**—Munich has lost another prominent medical man, following close on the death of von Ziemssen. Professor Hans Buchner died, April 5, of tuberculosis of the lungs, in his fifty-third year. He was at first a military medical officer until called to take Pettenkofer's place at the head of the Institute of Hygiene. He still maintained his connection with the army as surgeon-general "a la suite der armee." He was born in and spent most of his life in Munich. Among his latest contributions to science is his work on the prolonged local application of alcohol for inflammatory processes.

**Charlatans in Berlin.**—The recently-published statistics for 1897 state that there are 476 medical charlatans in Berlin, that is, one to every 4.6 physicians. Out of 123 male charlatans, 20 per cent. had been previously servants or day laborers; 40 per cent. artisans and only 24 per cent. from classes which presuppose an education above the lowest grades. Out of 125 women charlatans, 58 per cent. had been servants; 10 per cent. working women; 4.9 per cent. attendants on the sick, and 1.6 per cent. without previous occupation. The *Deutsche Med. Woch.* states that, whereas the population of Berlin has increased by 61 per cent. since 1879 and the number of physicians by 102 per cent., the number of charlatans has increased by 1367 per cent.

#### LONDON LETTER.

##### The Smallpox Epidemic.

The number of cases under treatment in the metropolitan hospitals, which had been 1542, 1567 and 1526 in the three preceding weeks, has declined still further to 1522; 376 fresh cases were admitted, against 450, 449 and 389 in the preceding weeks. The deaths from the disease, which had been 81, 53 and 61 in the preceding weeks, were only 54 last week. Since August 10 last, when the epidemic began, 5925 cases have occurred. Of these, 3712 have recovered, and 931 have died.

##### Leprosy in South Africa: Hutchinson's Conclusions.

Mr. Jonathan Hutchinson, whose departure for South Africa to investigate the mode of diffusion of leprosy we announced in *THE JOURNAL*, has returned and made a highly important communication to the *Times*. Later his researches will probably be communicated at greater length to the Royal Medical and Chirurgical Society. In addition to the large leper asylums on Robben Island (Cape Town) and at Emjuayua (Tembuland), he has visited many districts where the disease occurs, in order to investigate the domestic conditions of lepers. His inquiries establish the fact that the disease is very sparingly scattered over the whole of South Africa, and is by no means abundant anywhere. It chiefly affects the colored races, but a certain number of cases are to be found among the Dutch farmers. It was probably a new disease when the first cases (in members of the latter class) were recognized near to Cape Town 150 years ago. Since then it has gradually spread from the Cape Town district over the whole British territory, including the newly-annexed colonies of the Transvaal and the Orange Free State. In Natal it was a new disease as recently as 60 years ago, and is still met very sparingly. In Zululand it is as yet almost unknown. Mr. Hutchinson concludes that

the primary cause of the disease is the use as food of badly-cured saltfish. Such fish is prepared at Capetown and various places on the south and west coasts, and is sent inland in large quantities. While believing that this has been by far the chief agent in its diffusion, Mr. Hutchinson thinks that he has obtained conclusive evidence that leprosy may, in very exceptional circumstances, be communicated from person to person. He does not believe that it is either infectious or contagious in the proper sense of these words, but that it may be communicated by eating food contaminated by a leper's hands. This mode of transference can obviously occur only under the most careless conditions as to taking food and hence the explanation that the disease never spreads in leper asylums or in well-civilized communities, while it does so in Hottentot and Kaffir kraals. Its introduction into these kraals is usually effected by some laborer who has been into Cape Colony to work and returning home with the seeds of the disease has become a source of this kind of food contamination in his native place. The measures suggested for the prevention of the disease are first (and by far the most important) the legislative control of the fish-curing establishments; secondly, the diffusion of information as to danger of communication; and, thirdly, the establishment of small isolation homes into which lepers should be induced to go during the stage involving risk. Thus Mr. Hutchinson, as the result of his investigations, reaffirms the "fish-hypothesis" of the origin of leprosy—a doctrine which he has strenuously and persistently maintained for many years in the face of almost universal opposition of all the other authorities. He has also, against the general view, insisted that leprosy is not in the ordinary sense a contagious disease, pointing out that although a number of lepers live in England and mix freely with the population no case of contagion has ever been observed. This peculiar method of contagion from lepers through food is a new hypothesis, but it in no way invalidates (on the contrary, it confirms) Mr. Hutchinson's view of the non-contagiousness of leprosy in civilized life.

#### The Medical Profession in 1902.

The total number of practitioners for 1902 is 36,788, an increase of 434 over the total of 1901, which was 36,354. There are 6292 names on the London list, and 16,232 on the English provincial list. Scotland possesses 3645 medical men, as against 3569 in 1901, being an increase of 76; Ireland possesses 2587 medical men, as against 2575 in 1901, being an increase of 12; and Wales possesses 1183 medical men, as against 1165 in 1901, being an increase of 18. The registered medical practitioners abroad and of members of the naval, military and Indian medical services show a small increase upon the numbers of last year. The foreign and colonial names in 1901 numbered 3910, and this year number 3952, or an increase of 42; the members of the services in 1901 numbered 2798, and this year 2886, or an increase of 88.

#### The Campaign Against Malaria.

The Liverpool School of Tropical Medicine, which has organized a number of expeditions for the investigation of malaria in various parts of the empire, has asked the government to assist the expedition which is now endeavoring to improve the condition of Freetown, West Africa. The Governor of Sierra Leone has reported on the suggestion to increase the number of workmen who are working in Freetown under the superintendency of Dr. Logan Turner, that while anxious to give him every assistance he has decided after consultation with the principal medical officer that the best form in which that assistance can be given is for the government to undertake by degrees the surface drainage of those parts of the city most infested by mosquitoes. Arrangements have been made for the immediate surface drainage of a swampy portion of the grass fields district in which Dr. Taylor has worked. The cost of the work is estimated at \$2300.

#### Glanders in London.

A marked increase of the number of cases of glanders in London has recently taken place. During the past few weeks the number of cases reported have run over 40, last week alone totaling 45, as compared with 20 in the corresponding week of last year. There has always been considerable fluctuation in the returns as to glanders in London. For instance, the number which had fallen as low as 786 in 1885, increased to 2526 in 1892, and again fell to 845 in 1898. Last year the number was 1843. The use of mallein in detecting latent cases of the disease may be responsible for some of the recent increases. An unscrupulous owner of horses, when an outbreak occurs in his

stud, has all the horses which have been in contact with the diseased animals quietly injected with mallein, and if they show signs of glanders at once proceeds to sell them. If this is done to any large extent it would not be difficult to account for the present spread of the disease.

#### Gifts of a Patient to a Physician Invalidated.

An important case has just been decided in the law courts. The executors of a wealthy old lady, who died at 80, sought to recover from Dr. Price, who had attended her for 11 years, three sums of \$2500, \$500 and \$1000 given to him in the years 1899-1900. She left at her death property amounting to \$450,000, which she had inherited from her first husband. She provided for her second husband, made gifts to relatives in humble circumstances, left her house and grounds for a museum and public gardens, and made large bequests to charities. The executors made no charge of fraud or improper conduct against the doctor, but claimed that because of the relations of physician and patient existing between the parties, in the absence of independent advice obtained by the donor, a presumption of undue influence existed and that such gifts should not stand. The doctor who had been paid for his services in the ordinary way the sum of \$1560, explained fully the circumstances in which the gifts were made. The largest sum, \$2500, was a gift partly in recognition of his exceptional services as medical attendant, and partly in recognition of his consent to act as trustee of the institution to be founded by the patient in memory of her husband. The \$500 was a Christmas present, and the \$1000 was given to replace a brougham which had been injured in a carriage accident. The judge ordered the doctor to repay the whole of the gifts, \$4000. He ruled that: "It has been laid down that the relation of patient and physician is a confidential relationship, and where it exists, as it did in this case, the donor must have had competent and independent advice before a gift can be supported." The law applies to other confidential relationships, such as those of clergy and solicitors. In the present case the doctor was mulcted in costs, which the *Lancet* thinks was rather hard. As the contention arose out of acts of the testatrix, her estate should have borne the costs. The *Lancet* does not see why a patient's gratitude should not be manifested to her doctor otherwise than by fees which can be claimed, but care should always be taken that the patient has independent advice. If the doctor in the present case had done this, the validity of the gifts could not have been questioned.

## Book Notices.

THE STANDARD MEDICAL DIRECTORY OF NORTH AMERICA, Consisting of Twelve Parts, Including Directory of Physicians of North America, Medical Colleges, Medical Service of the United States, Medical Societies, Medical Practice Acts, Medical Publications (Including Books and Periodicals), Mineral Springs, Drugs and Medicines, Medical and Surgical Products, Manufacturers and Life Insurance Companies. Handsomely Bound in Red Buckram, 824 Pages, Imperial Octavo. Price, \$10.00. Chicago: G. P. Engelhard & Co.

This directory is divided into twelve parts, the first of which takes up medical colleges, present and extinct, prefaced by a short chronological sketch of medical education. Part second, which makes up the greater part of the book, is on the same general principle as Polk's Directory. An improvement over the latter is that the index of names of colleges is on the front inside-cover page instead of being in the body of the work; furthermore, the colleges in each state are numbered consecutively. An exceedingly important omission is that of the name-index which forms so valuable a guide in looking up the addresses of physicians whose names only are known. The directory of physicians is, so far as we can judge, in the main, correct and complete. The succeeding sections of the book are devoted to the medical service of the United States—the army, navy, marine-hospital service, pension examination service, etc.; medical societies—national, state, district, county, and city; medical legislation, including the text of the medical practice acts of all of the states, a synopsis of the statutes, the board regulations and rules, and the personnel of the state boards of health, and boards of medical examiners; medical publications by authors' names; medical books by subjects, medical directories and medical libraries; hospitals and sanatoria, arranged by states; mineral springs and their distribution; drugs and medicines; medical and surgical products; manufacturers and life insurance companies and fraternal and assess-

ment organizations. It is, of course, too much to expect that a work of this nature could be issued without interleaved advertisements, but this is much to be desired. An interesting page is that which presents the population of the countries of North America, the number of physicians and the proportion of physicians to ten thousand of population.

**A PRACTICAL MANUAL OF INSANITY.** For the Student and General Practitioner. By Daniel R. Brower, A.M., M.D., LL.D., Professor of Nervous and Mental Diseases in Rush Medical College, in Affiliation with the University of Chicago, and in the Post-Graduate Medical School, Chicago; and Henry M. Bannister, A.M., M.D., formerly Senior Assistant Physician, Illinois Eastern Hospital for the Insane. Cloth. Price, \$3.00 net. Handsome octavo of 426 pages, with a large number of full-page inserts. Philadelphia and London: W. B. Saunders & Co. 1902.

The average physician is only incidentally interested in the controversial questions relating to psychiatry; what he needs and asks for is practical information for every-day practice, something to help him solve the problems of managing these unhappy cases. The book before us is an attempt to supply this need and to give this help. It is not intended for the alienist or for those who want an exhaustive treatise on insanity. It is a practical presentation of the subject for practical use. While it is not encumbered with controversial matters or padded with a lot of theories it is sufficiently full and complete to meet every need. Dogmatic assertions are avoided and, when disputed points are considered, the views of others are given as well as those of the authors. The classification of insanity is a stumbling block to most authors of works on the subject. It is impossible to classify the various forms of insanity in a manner satisfactory to all and yet, as the authors say, it is a necessity for the ordering of ideas. They devote quite a chapter to the subject giving the classifications of Ziehen, Kraepelin, Regis, Agostini and others and adopt a modification of that of Kraepelin. A few minor typographic errors are to be found, but not more than is usual in a new edition. The most serious one is in the comparative table of classifications on page 149, where the word "verwirrtheit" is used where it should be "verneektheit." However, this will not mislead those who read the text.

The subject is presented in an attractive and simple style, making the reading a pleasure, which is more than can be said of most works on insanity. We predict that it will prove one of the most popular works on the subject that has been placed before the profession for years.

**A CIVILIAN WAR HOSPITAL.** Being an Account of the Work of the Portland Hospital, and of Experience of Wounds and Sickness in South Africa, 1900. With a Description of the Equipment, Cost and Management of a Civilian Base Hospital in Time of War. By the Professional Staff, Anthony A. Bowlby, C.M.G., F.R.C.S., Senior Surgeon, Howard H. Tooth, M.D., C.M.G., F.R.C.P.; Cuthbert Wallace, M.B., B.S., F.R.C.S.; John E. Calverley, M.B., B.S., M.R.C.S.; and Surgeon-Major Kilkelly, C.M.G., Grenadier Guards, Principal Medical Officer and in Military Charge. With Numerous Illustrations. Cloth. Pp. 341. Price, \$4.00. New York: Longmans, Green & Co. 1901.

This work contains in detail the work of the Portland Hospital, which was the first of the civilian hospitals to be equipped and sent to South Africa after the opening of the Boer war. It was probably the first voluntary hospital attached to the British army at the front. After describing the personnel, equipment and interior economy of the hospital, the authors describe the work done by this hospital and its career in the field. The medical work done by the hospital was chiefly in enteric and typhoid fevers; the next most frequent diseases being diarrhea, dysentery and diseases due to exposure. The surgical work of the hospital is described by Mr. Bowlby and Mr. Cuthbert Wallace and deals first with weapons and projectiles, the surgical aspects of modern rifle fire, bullet wounds in general with their characteristics, and then takes up special wounds of the bones, joints and blood vessels and then regional injuries. The volume is copiously illustrated and is completed by a series of appendices, containing specific details, forms and blanks, staff of the hospital, etc.

**HYGIENE FOR STUDENTS.** By Edward F. Willoughby, M.D., Lond., Diploma in State Medicine of the London University. Cloth. Pp. 563. Price, \$1.25. London and New York: The Macmillan Co. 1901.

This is practically the fourth edition of the *Principles of Hygiene*, published in 1884, 1888 and 1893. This is specially adapted to English professional examinations and the arrange-

ment is made accordingly, each chapter ending with a series of questions on the subjects discussed. The book is one that we should consider well adapted for students' use, and, while arranged especially for English students, it might be used with profit in this country. It covers the whole ground of hygiene, not only the more exclusive medical side, but also the subjects of vital statistics, demography, meteorology, etc. We find here and there a little that may be open to question and some matters may arise in this country that are not fully treated of, which is to some extent a defect in the work for American students. Taking it altogether, it is a valuable book and one well worthy the attention of the practicing physician as well as the student.

**OFFICIAL LIST OF LEGALLY QUALIFIED PHYSICIANS, STATE OF ILLINOIS.** Published by the State Board of Health, March, 1902. Paper Edition and Cloth Edition. Springfield: Illinois State Register Co.

This is a list of the 20,000 physicians who have received certificates from the State Board of Health from July 12, 1877, to March 1, 1902, except those known to be deceased or whose certificates have been revoked. There are given the school of practice, date of license and present address if in Illinois.

A valuable feature of the book is the text of the laws governing practice in Illinois and a summary and tabulation of the laws in all the other states and territories. This is also published separately in a pamphlet which will be appreciated by the applicant for license. A list of accredited medical colleges and information for Illinois applicants for license complete the contents.

**SYPHILIS: A Symposium.** Cloth. Pp. 122. Price, \$1.00. New York: E. B. Treat & Co. 1902.

The papers contained in this volume appeared recently in the *Interstate Medical Magazine* and constituted one of the special numbers which have been sent out of late by that publication. As an up-to-date statement of the practical facts regarding syphilis it makes an exceedingly useful and authoritative little work. Some of the papers have been already noticed in THE JOURNAL abstracts and we need not review them more fully here.

**COMPEND OF GENERAL PATHOLOGY.** By Alfred Edward Thayer, M.D., Assistant Instructor in Gross Pathology, Cornell Medical College. Containing 78 Illustrations, Several of Which Are in Colors. Cloth. Pp. 321. Price, \$0.80. Philadelphia: P. Blakiston's Son & Co. 1902.

This is one of the well-known series of quiz compends published by Blakiston. The illustrations are specially good. Of course, such a work as this is very inadequate for thorough work, but as a reminder to the memory it has its value.

## State Boards of Registration.

**In Georgia,** licenses were given to 74 out of 78 applicants at Atlanta, April 5.

**Utah Board Adds to the List.**—The session of the Utah examiners on April 7 and 8 added to the licensed physicians of that state 7 out of 10 applicants and 11 of the 12 prospective midwives were licensed.

**Indiana Board Gives Certificates.**—Eight recent graduates were licensed to practice by the Indiana Board of Medical Registration and Examination at its April meeting at the capitol. A candidate who presented a diploma from a school of magnetic healing at Nevada, Mo., for which he had studied and labored for three weeks, was asked a few questions for the board's amusement. He was advised to try some other calling or else to study a few years.

**The Colorado State Board of Medical Examiners** passed on the credentials of 43 applicants to practice medicine. Thirty-eight were granted licenses on their diplomas according to the statute requiring the board to recognize as sufficient evidence of ability diplomas from recognized medical colleges. Four passed examinations and were licensed, three of them non-graduates and one a graduate of a medical college requiring only a three years' course. There were 80 written questions in 3 subjects and 70 per cent. was necessary to pass. The application of G. L. Hagen-Burger, No. 3611, was refused, it having been shown by conclusive evidence to the board that the purported diploma from Kiel that he presented was fraudulent.

The dean of that university and the U. S. Consular agent at Kiel report it to be a forgery of the diploma of one Dr. Otto Tretow of that date on the same thesis "Zwei Falle von Luxatio Lentis Congenita." The secretary, Dr. S. D. Van Meter, is prosecuting the man, and will be glad to have the assistance of any graduate of Kiel who can aid him. The man has been arrested, but technicalities may prevent conviction.

**North Dakota Examiners** at Grand Forks, April 1 to 3, tested 12 applicants and found 11 could answer 75 per cent. of the questions in the 13 subjects. The examination was written.

## Married.

E. A. DYE, M.D., to Miss Nina Smith, both of Vienna, Ohio, April 10.

A. J. KIMMONS, M.D., to Miss Mary Guy Cowan, both of Shelbyville, Tenn.

HENRY G. HART, M.D., to Miss Selma N. Alpiner, both of Chicago, April 15.

ALEXANDER C. SMITH, M.D., Sterling, Ill., to Mrs. Georgia Hilger, at Chicago.

CHARLES CLARK FOWLER, M.D., to Miss Charlotte Frye, both of Des Moines, Iowa, April 9.

CHARLES F. BAUMEISTER, M.D., Panama, Iowa, to Miss Lida Bard Moore, of Chicago, April 9.

ARNOLD T. ADDY, M.D., Middleport, N. Y., to Miss Mary Waldrum, of Toronto, Ontario, April 14.

HARRY P. RITCHIE, M.D., St. Paul, Minn., to Miss Elizabeth Winter, of Chicago, at St. Paul, April 24.

ARTHUR P. SHELLMAN, M.D., Binghamton, N. Y., to Miss Jennie E. Gibson, of South Pulteney, N. Y., April 15.

HENRY CYRIL GOODMAN, M.R.C.S., L.R.C.P., Kasr-el-Aini Hospital, Cairo, Egypt, to Miss Sue Clay of Paris, Ky., April 22.

SAIING SIMON, M.D., secretary of the staff of the National Jewish Hospital for Consumptive, Denver, to Miss Sara E. Lowenstein of Memphis, Tenn., April 9.

## Deaths and Obituaries.

Franklin A. Meacham, M.D. University of Virginia, Charlottesville, 1889, whose death was noted under "General News" last week, was the son of Major Meacham, who was for many years post surgeon at Fort Douglas, Utah. After completing his medical studies he practiced in Salt Lake City and was a

member of the Staff of Holy Cross Hospital. At the outbreak of the Spanish-American war he was appointed surgeon of volunteers, with the rank of major, and served with his regiment in Cuba. He made especial study of camp hygiene and was an authority on that subject. He was ordered to Manila and served in the Chinese expedition in 1900. On his return to Manila he was detailed as assistant to Major L. M. Maus, insular health commissioner. Heart failure, caused by overwork on the cholera cases, was the cause of his death, at the age of 39.

**Luther B. Grandy, M.D.** College of Physicians and Surgeons, New York, 1890, is reported as having died at Lipa, Batangas, Luzon. He was a native of Tennessee and practiced at Atlanta, Ga., until the Spanish-American war, through which he served as major-surgeon of the Third Georgia Infantry, U. S. V. He then went to Manila as an acting assistant surgeon, and was later assigned to the Thirty-fifth Infantry, U. S. V., as major-surgeon, and died while on duty with his command, aged 42.

**Richard R. Ricker, M.D.** Medical School of Maine, Bowdoin College, Brunswick, 1847, one of the oldest physicians of Lewiston, who served through the Civil war as assistant surgeon of the Twenty-third and Thirty-first Maine Volunteer Infantry, and afterward located in Lewiston, where he was for several terms a member of the city council, and for six years, city physician, died at his home in that city, from paralysis, April 14, after an illness of three days.

**George M. Ramsey, M.D.** Jefferson Medical College, Philadelphia, who practiced in New York City until the outbreak of the Civil war, through which he served as surgeon of the 95th New York Volunteer Infantry, and soon after retired from practice on account of deafness, contracted while in the service, died at his home in Washington, Pa., from infirmities incident to old age, April 13, aged 82.

**Horace Tupper, M.D.** University of Buffalo, N. Y., 1862, a pioneer physician of Bay County, Mich., who served two years in the Civil war, until compelled to resign on account of ill-health, and who afterward resided in Bay City, died at his home in that city, April 16, from cancer, after an illness of four months, aged 71.

**John F. Dowd, M.D.** Dartmouth Medical College, Hanover, N. H., 1896, of Manchester, N. H., a member of the Manchester Medical Association and of the New Hampshire State Medical Society, died at Sacred Heart Hospital, Manchester, April 12, from pneumonia, after an illness of one week, aged 37.

**Eugene C. Hoge, M.D.** Long Island College Hospital, 1872, one of the best-known physicians of Wheeling, W. Va., a member of the Medical Society of the State of West Virginia, died in Wheeling from meningitis, after an illness of several weeks, April 10, aged 54.

**T. H. Sharpneck, M.D.** Jefferson Medical College, Philadelphia, 1872, of Jefferson, Greene County, Pa., a member of the American Medical Association, died suddenly from paralysis while making a professional call at Khedive, April 12, aged 58.

**Braxton D. Cox, Jr., M.D.** Kentucky School of Medicine, Louisville, 1892, a prominent young physician of Jackson, Ky., was shot and instantly killed while on his way home from his office, April 13. So far, his assassin has not been found.

**Theodore W. Nellis, M.D.** Albany (N. Y.) Medical College, 1881, died at his home in Albany, April 14, after a long illness. The Medical Society of the County of Albany held a special meeting, April 15, and passed suitable resolutions.

**Joseph T. V. Blocksom, M.D.** Jefferson Medical College, 1871, of Wilmington, Del., who had been an inmate of the State Hospital for the Insane, Farnhurst, for several weeks, committed suicide at the hospital, April 15, aged 55.

**Matthew Campbell, M.D.** Medical School of the Valley of Virginia, Winchester, Va., 1852, a retired physician, for many years a practitioner of Fairmont, W. Va., died at his home in Parkersburg, W. Va., April 12, aged 84.

**John H. McIntyre, M.D.** Jefferson Medical College, Philadelphia, 1864, one of the oldest and best-known physicians of St. Louis, Mo., died from asthma at his residence in that city, after a long illness, April 10, aged 69.

**Charles H. Carter, M.D.** Rush Medical College, Chicago, 1880, a native of Rock Island, Ill., who practiced for several years and then was obliged to go to California for his health, died at Pasadena, April 5, aged 49.

**William L. Bain, M.D.** Trinity Medical College, Toronto, 1888, who served during the Riel rebellion in the northwest, and

practiced medicine in Toronto until 1893, when he moved to Chicago, died at his home, April 13.

**Charles E. Bartlett, M.D.** Berkshire Medical College, Pittsfield, Mass., 1844, a resident of Battle Creek, Mich., since 1845, died at his home in that city from pneumonia, April 14, after a short illness, aged 82.

**Marcellus M. White, M.D.** Hospital College of Medicine, Louisville, Ky., 1895, of Cumberland Gap, Tenn., died in Fannin County, Texas, April 13, after a long illness, aged 39.

**Moses H. Detwiler, M.D.** Jefferson Medical College, Philadelphia, 1870, one of the oldest physicians of Bedford County, Pa., died, April 15, at his home in Hopewell.

**Alvin A. Moore, M.D.** University of Cincinnati, 1886, of Parker's Landing, Pa., died from tuberculosis at Kenton, Ohio, after a long illness, April 14, aged 41.

**Andrew G. Toven, M.D.** College of Physicians and Surgeons, New York, 1890, of New Britain, Conn., was found dead in Hartford, Conn., April 11, aged 35.

**William F. Shepard, M.D.** Medical School of Maine, Bowdoin College, Brunswick, 1871, died at his home in Bangor, from pneumonia, April 12, aged 57.

**Edward P. Gordon, M.D.** Toronto University Medical College, 1890, died recently in San Francisco, Cal. He practiced for several years in Toronto.

**David A. Plank, M.D.** Jefferson Medical College, 1870, of St. Clairsville, Pa., a veteran of the Civil war, died, April 12, at his home, aged 64.

**Joseph H. Gallagher, M.D.** Long Island College Hospital, Brooklyn, 1898, died at his home in Brooklyn, from pneumonia, April 9, aged 26.

**Charles B. Robertson, M.D.** University of Buffalo, N. Y., 1884, died from consumption at his home in Towlesville, N. Y., April 4, aged 49.

**John Dixon, M.D.** Jefferson Medical College, Philadelphia, 1860, of Fayetteville, Ala., died at Talladega, April 15, after a long illness.

**Jonathan Faust, M.D.** Jefferson Medical College, Philadelphia, 1867, died at his home in Zieglersville, Pa., April 14, aged 60.

**Robert W. Dailey, M.D.** University of Pennsylvania, Philadelphia, 1842, died at his home in Romney, W. Va., April 12, aged 80.

**George A. M. Cooke, M.D.** Tulane University, New Orleans, 1881, died at his home near Washington, La., April 10, aged 47.

**Jessie Florence McKay, M.D.** University of Buffalo, died recently in New York City, from pleuro-pneumonia, aged 41.

**P. A. Davis, M.D.** Willamette University, Salem, Ore., 1871, died, the second week in April, at his home in Silverton, Ore.

**James T. McKillop, M.D.** Trinity University, Toronto, Ont., 1889, died at his home in Wardsville, Ont., April 9, aged 41.

**George S. Smith, M.D.**, of Pinckneyville, Ill., died at his home, April 2, aged 85.

**John F. Biggs, M.D.**, died at his home in Center Point, Ark., recently.

## New Instruments.

### THE PUNCTUMETER, FOR MEASURING THE RANGE OF ACCOMMODATION.

J. G. HUIZINGA, M.D.  
GRAND RAPIDS, MICH.

The punctumeter is an instrument for ascertaining the range of accommodation. Its name signifies a point-measurer, i. e., to measure the far and near points of vision. The difference between these two points equals the range of accommodation. For several years I have been impressed with a lack of reliable methods for making these measurements. No instrument for obtaining this information being in existence, I began to study whether it would not be possible to have one constructed on scientific principles. After the usual history of trials and failures I am at last able to present to the profession an instrument which I believe to be absolutely reliable. It is so constructed that it can also be used as a rapid test for any of the errors of refraction and in this respect I know of no instrument that is superior to it.

A 10 D. convex lens is placed at a distance of 9.7 cm. from the end of the instrument which rests against the edge of the orbit. This brings the lens practically 10 cm. from the nodal point of the eye. A test card, with figures of appropriate design and size, is placed 10 cm. behind this lens and thus occupies one of the points of the conjugate foci, the other

being the nodal point of the eye. This test card can be moved back and forward. The difference in centimeters between the greatest and least distances at which this test type can be distinctly seen is the measure of the range of accommodation.

### INSTRUMENT TO FACILITATE THE PLACING OF DRAINAGE IN AFTER-TREATMENT OF SUPPURATIVE APPENDICITIS.

A. E. SPALDING, M.D.  
LUVERNE, MINN.

The effort to place drainage at the bottom of the sinus after removal of the primary drain is sometimes difficult and often painful to the patient. As the gauze adheres to the sides

of the sinus, considerable force has to be used before it can be properly carried to the bottom of the cavity.

The necessity for an instrument for the purpose of facilitating the placing of drainage led to a crude production which I hammered out of a white metal spoon and which I have frequently used during the past four years.

Having demonstrated to my own satisfaction the practicality of such an instrument, I have recently had made for me

a set of four instruments,  $\frac{1}{4}$ ,  $\frac{5}{8}$ ,  $\frac{1}{2}$  and  $\frac{3}{8}$  of an inch in diameter by 5 inches in length. The large size is the one ordinarily used for the first dressing, diminishing the size as the sinus narrows.

The manner of using is to place the convexity toward the median line; gently force the instrument to the bottom of the cavity; then draw it toward the median line as you would a retractor, and with long dressing forceps grasp a strip of the gauze which is then carried to the bottom of the cavity and released. After packing loosely, pressure is used with the dressing forceps on the top of the gauze to prevent misplacement while withdrawing the instrument. Should Morris' wick drain be used instead of gauze, the principle and utility of the instrument will be the same.

While this is a very simple device, I am confident it will be found a great aid to the proper carrying out of the treatment required in such cases.

Their use need not be restricted to the purpose above indicated, but will be found convenient in certain gall-bladder cases or in any abdominal case requiring subsequent drainage, as well as in suprapubic cystotomy as an exploratory instrument.

## Miscellany.

**American Journalism.**—America can now boast of seven great weeklies, 260 monthlies, and some 25 other journals of various kinds. According to the *American Medical Journalist*, the following new journals were born within the year: *American Medicine*, Philadelphia; *Detroit Medical Journal*; *Texas Medical Gazette*, Fort Worth, Tex.; *Journal of New York Medical Association*, Albany; *Journal of Surgical Technology*, New York City; *Doctors' Magazine*, Alma, Mich.; *Regular Medical Visitor*, St. Louis.

**What One Society Does.**—In Minnesota a local medical society has by practical experiment carried to successful conclusion shown what can be accomplished by our profession in a business way. The Ramsey County Medical Society owns and publishes the *St. Paul Medical Journal*, whose excellence is everywhere well recognized. The journal has been earning a profit for the society, and has collected a library of 3500 or 4000 volumes which is open to the profession. There is operated in connection with it a clinical laboratory, and a profit has been made out of the preparation and sale of catgut. In view of the marked success of this experiment there is no inherent reason for holding that the profession can not in other cities conduct in a coöperative way those industries with which it is so closely allied.—*Cleveland Med. Journal*.

**A Lay View of Physicians.**—"Doctors do not call themselves philanthropists, yet they practically accomplish more in that line than men of any other vocation. What a great, though quiet, force they have been in the building of the West! If the full story of their labors and sacrifices in Missouri could be told the record would touch every heart and impress every mind with its value and magnitude. Doctors are men of sentiment, wholesome and high-minded sentiment, suited to the needs and advancement of everyday life. They know few holidays and often devote those they have to greeting a noble old teacher, as they did last night. (This refers to the Gregory banquet.) They work in the shadows of human existence, but always toward the light. Americans could get along without politicians, being born that way, but the learning and goodness of the medical profession do not come by nature."—Editorial, St. Louis *Globe-Democrat*.

**Hahnemann on Sectarianism.**—We have all heard and read of people who are more royalistic than the king himself; and so sectarians of all descriptions frequently become more zealous than the founders themselves. Some of the narrow-minded homeopaths object to the liberalizing movement which has been making itself felt of late and which induces many Hahnemannians to drop their sectarian names. Such ones will do well to read and ponder over the words of Hahnemann, which will be found in his "Lesser Writings." They are in substance as follows: "The motto of a sectarian name is a bar to sober, calm, scientific investigation; it only rouses the an-

tagonistic spirit to a fierce, volcanic flame. Truth and welfare of humanity should be the only motto of the true followers of the art, and a brotherly, peaceful reunion, without slavish adherence to any sectarian leader, should be our only watchword, if we do not wish to see that little good that we have accomplished completely sacrificed to party spirit and discord."—*Merck's Archives*, March.

**Movement of the Population in France.**—An editorial in the *Presse Medicale* states that the recent census shows that France has gained 444,613 inhabitants during the last five years, more than two and a half times the gain during the preceding years. During the corresponding period Germany has gained 140 for every 1000 inhabitants; Austria 96, and Great Britain 100; while the gain of France has been only 16 for every 1000. The French cities have increased their population by 458,576 during this period, so that in spite of the total gain, the country outside of the cities has actually lost inhabitants. The departments which contain the largest cities, Seine and Rhône, average 256 deaths from tuberculosis out of every 1000 deaths, while the rural districts average only 68. Out of this proportion of 256 a very large number, if not the majority, are young men, *déracinés*, transplanted from their natal soil, from the vast spaces and pure air of the country, who have not been able to acclimate themselves to the conditions of crowded city life.

**Superiority of Goats' Milk.**—The French National Société d'Acclimatation and the Paris municipal laboratory have been making extensive tests of goats' milk. The results have demonstrated—according to an article in the *Journal de Méd.*—that the goat deserves the highest rank among all milk-producing animals. Their milk contains 22 to 40 gm. of casein to the liter and it is identical in all its properties with the casein in human milk. The species of goat and the period of the lactation determine the richness of the milk. The molecules of butter and casein are extremely minute and the milk is rich in natural phosphates. As the goat is refractory to tuberculosis, the danger of infection from this source is avoided by the use of goat milk. A Paris physician, Dr. G. Barbellion, has opened a goat milk depot and calls upon his confrères elsewhere to follow his example and thus remedy one of the worst scourges of our epoch. The medical control of the establishment guarantees the aseptic bottling of the milk as soon as drawn. Results have shown the way in which young and old thrive on this pure, physiologic, living natural food.

**Liquid Soap.**—An excellent formula for liquid soap for surgical and toilet purposes is the following, from the *Am. Jour. Pharmacy*:

|                           |     |
|---------------------------|-----|
| R. Cottonseed oil .....   | 300 |
| Alcohol .....             | 300 |
| Water .....               | 325 |
| Sodium hydrate .....      | 45  |
| Potassium carbonate ..... | 10  |
| Ether .....               | 15  |
| Carbolic acid .....       | 25  |

To the oil in a bottle of sufficient size, add 100 c.c. of water and 200 c.c. of alcohol; add the sodium hydrate and shake occasionally until it saponifies; then add the remainder of the alcohol and the potassium carbonate dissolved in the rest of the water; lastly add the carbolic acid and ether. Keep well corked. It will solidify at a temperature below 10 C. A few drops will make a copious and lasting lather with great detergent qualities, excellent for instruments, preparation of patients, cleansing of the hands, especially when stained or odorous, and for other surgical uses. By substituting an essential oil for the ether and carbolic acid, a scented toilet soap is made. This makes an unequalled shaving soap and shampoo, according to Pharmacist M. I. Wilbert, of the German Hospital, Philadelphia.

**Javanese Method of Narcosis.**—L. Steiner describes in the *Arch. f. Schiff's- u. Tropen-Hygiene*, v. 12, a method of narcosis which has been long practiced in Java. The hands are placed on the neck of the subject, the fingers meeting at the back, and the carotid artery is briefly compressed with the thumbs, back of and a trifle below the lower jaw. The artery is pressed back toward the spine. Only 5 out of 30 subjects failed to

respond to his application of this maneuver. The head falls back and the subject seems to be in a profound slumber, from which he awakes in a few minutes as if suddenly aroused. The effect can not be due to suggestion, as the same maneuver avoiding the arteries, fails to produce any effect. The procedure is called by a Javanese term which signifies "compression of the sleep vessel." The popular name for the carotid artery in Russian, by the way, is also the "sleep artery"; and "carotid" is derived from the Greek *karos*, sleep. He has never witnessed or heard of any accidents from this method of narcosis which is widely practiced on the island, frequently associated with general massage. The patients do not vomit, and there is no incontinence of urine or feces. He opened an inguinal abscess in one case while the patient was unconscious. He is inclined to advocate this absolutely harmless method of narcosis as worthy of a place in surgery, on account of the rapidity with which it can be accomplished and the rapid awakening. The procedure may also prove effective in combating cephalalgia, vertigo and insomnia.

**The Relation of Malignant to Rheumatic Endocarditis.**—At the Royal Medical and Chirurgical Society Dr. F. J. Poynton and Dr. Alexander Paine read an important paper on this subject. The relationship between the two diseases was, they believed, a very close one, and this was especially true of certain cases of malignant endocarditis which were associated with a previous history of rheumatic fever, and during the course of which rheumatic manifestations were apt to occur. Now that rheumatic valvulitis is known to be infective, "malignant endocarditis" is, they think, a more accurate term than "infective endocarditis." The question arises whether some of these malignant cases are not really rheumatic. The possibility of complete proof has been heretofore impossible since an exciting cause of rheumatic fever was unknown. The evidence in favor of such a cause being a diplococcus is now extremely strong. The writers' research has led to the conclusion that there is a group of cases of malignant endocarditis rheumatic in origin. A diplococcus can be isolated from cases of malignant endocarditis which grows in pure culture and reproduces that disease in rabbits, and resembles the diplococcus of rheumatic fever in its morphology and cultural characteristics. Moreover, the diplococcus of rheumatic fever produces malignant endocarditis in rabbits on the one hand, and the diplococcus from certain cases of malignant endocarditis produces rheumatic fever in rabbits on the other. Finally every grade of valvulitis, from simple or malignant and vice versa, can be produced by these two diplococci. A valuable series of macroscopical and microscopical specimens, lantern slides, and drawings were exhibited in support of these statements.

**Primary Tuberculosis of the Cervix Simulating Cancer.**—At the Obstetrical Society, London, Dr. Lewers related the case of this very rare condition. A married woman, aged 36, had never been pregnant. For nine months there had been a blood-stained and slightly offensive vaginal discharge. Bleeding was noticed after coitus and after using a vaginal syringe. The general health began to fail about twelve months before she came under observation, but she did not think she had lost flesh. An aunt had died of consumption. The vaginal portion of the cervix seemed to be in a condition identical with what was found in many cases of cancer. It was the seat of a friable growth which bled easily on examination. The uterus was freely movable. Thinking the case was one of cancer of the cervix, Dr. Lewers performed vaginal hysterectomy on Jan. 30, 1896. The patient made a good recovery. In November, 1901, she enjoyed "fairly good health." Microscopic examination of the growth showed that it was tuberculous.

**Medicine Among the Ancient Inhabitants of Peru.**—The *Cronica Medica* of Lima published during the last months of 1901 the graduating thesis of D. E. Laverria which is devoted to this subject. He pays particular attention to the herbs used by the ancient Incas in various affections, some of them still in use to-day. He mentions that anesthesia was induced by an exceptionally strong alcoholic drink when servants were to be killed at the death of their masters and also when the ears of young warriors were mutilated. Ancient Spanish

writers dwell upon the fondness of the Incas for bathing, which they believed washed away their sins as well as various diseases. Another cause for their love of hydrotherapy is suggested by a royal decree calling for a certain tax tribute from all the people. When the subjects were absolutely too poor to pay it in money they must pay it with a certain number of body lice in token of vassalage. The Inca names of certain diseases indicate their nature, as for instance "burning breathing." Medicine was practiced mostly by the priests and the trephining of the skull was a measure adopted to allow the egress of the evil spirit causing the disease. Muniz found trephined skulls in the proportion of 2 per cent. in his collection of 1000 skulls. Some of the subjects evidently survived and others died under the operators' hands, to judge from the unfinished condition of the wound.

**Cure of Excessive Sweating of the Feet.**—Gorodtzeff writes to the *Voenna-Med. Journal* that he has found ordinary kitchen soap the most reliable and best treatment of excessive sweating of the feet and the resulting ulcers. The feet are bathed in tepid water and the skin—between the toes and wherever there is sweating—is rubbed with a piece of moistened soap until a thin layer remains on the skin. The stockings and shoes are then put on without wiping the feet. The procedure is repeated once a week or more or less frequently, and in his extensive civilian and army experience the most inveterate and fetid sweats were thus conquered in every instance. Wearing ventilated shoes during the summer hastens the cure.

**Treatment of Smallpox with Brewers' Yeast.**—The favorable effect of yeast in furunculosis suggested to S. Arieti of Nice that it might be useful also in smallpox. The *Semaine Méd.* of February 19 states that it seemed to have an actual abortive influence in the two cases in which he tried it. Both were confluent cases and recovered rapidly after the administration of five or six teaspoonfuls of fresh yeast every day, with no other treatment. The pustules healed promptly without supuration, fever or pitting.

**Desiccated Serum for the Biologic Blood Test.**—J. Hausner has found that it is possible to preserve the sera of various animals to use in the Deutsch and Uhlenhuth biologic test for blood. He poured the sera in a thin layer in Petri dishes and dried them in the oven in the dark. The powder thus obtained proved extremely effective.—*Med. Obscure*, December, 1901.

## Societies.

### COMING MEETINGS.

American Medical Association, Saratoga Springs, N. Y., June 10 to 13.

Association of American Physicians, Washington, D. C., April 29 to May 1, 1902.

American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.

International Association of Railway Surgeons, St. Louis, Mo., April 30 and May 1 and 2, 1902.

American Gastro-Enterological Association, Washington, D. C., May 2, 1902.

Nebraska State Medical Society, Omaha, May 6-8, 1902.

Texas State Medical Association, Dallas, May 6-9, 1902.

Kansas Medical Society, Lawrence, May 7-9, 1902.

American Therapeutic Society, New York City, May 13, 1902.

Utah State Medical Society, Salt Lake City, May 13-14, 1902.

Oklahoma Territory Medical Association, Oklahoma City, May 14, 1902.

Arkansas Medical Society, Little Rock, May 13-15, 1902.

New Hampshire Medical Society, Concord, May 15-16, 1902.

Illinois State Medical Society, Quincy, May 20-22, 1902.

American Surgical Association, Albany, N. Y., May 20-22, 1902.

Medical Association of the State of Missouri, St. Joseph, May 20-22, 1902.

Kentucky State Medical Society, Paducah, May 7-9, 1902.

Arizona Medical Association, Tucson, May 21-22, 1902.

Medical Society of West Virginia, Parkersburg, May 21-23, 1902.

Medical Association of Montana, Anaconda, May 21-22, 1902.

Iowa State Medical Society, Des Moines, May 21-23, 1902.

**Cass County (N. D.) Medical Society.**—At the annual meeting of this Society, Dr. Isaac N. Wear, Fargo, was elected president.

**American Therapeutic Society.**—This Society will hold its third annual meeting at the New York Academy of Medicine, May 13, 14 and 15, under the presidency of Dr. Reynold Webb Wilcox, New York City.

**Southern Idaho District Medical Society.**—This Society convened at Boise, April 3. Dr. Burpee L. Steeves, Weiser, was elected president; Dr. Lewis C. Bowers, Boise, vice-president, and Dr. Hubert A. Castle, Pocatello, secretary and treasurer.

**Cumberland County (N. J.) Medical Society.**—At the annual meeting of this Society, held in Bridgeton, Dr. H. Garrett Miller, Millville, was elected president; Dr. John C. Applegate, Bridgeton, secretary, and Dr. Joseph Tomlinson, Bridgeton, treasurer.

**Cuyahoga County (Ohio) Medical Society.**—The annual meeting of this Society was held, April 3, when Dr. John P. Sawyer was elected president; Dr. Frederick C. Herriek, vice-president; Dr. George W. Moorehouse, secretary, and Dr. Charles G. Foote, treasurer.

**Perry County (Ind.) Medical Society.**—This Society, at its annual meeting held in Tell City, elected Dr. Charles M. Brucker, Tell City, president; Dr. Henry G. Weiss, Lamar, vice-president; Dr. Claude T. Hendershot, Canneton, secretary, and Dr. James B. Bennett, Derby, treasurer.

**San Diego County (Cal.) Medical Society.**—At the annual meeting of this Society, April 4, at San Diego, Cal., the following officers were elected: President, Dr. William M. Cummings; vice-president, Dr. Peter J. Parker, and secretary and treasurer, Dr. Thomas L. Magee, all of San Diego.

**Albany County (N. Y.) Medical Association.**—The annual meeting of this Association was held at Watervliet, April 1. Dr. William E. Lothridge, Verdox, was elected president; Dr. Adam T. Van Vranken, Watervliet, vice-president, and Dr. Martin J. Zeh, Watervliet, secretary and treasurer.

**Edwards County (Ill.) Medical Society.**—The physicians of Edwards County met at Albion, April 8, and effected a permanent organization with the following officers: Dr. William E. Buxton, Samsville, president; Dr. John S. Williams, Albion, vice-president, and Dr. James H. Lacy, Albion, secretary.

**Tipton County (Tenn.) Medical Society.**—This Society, originally formed in 1876, was reorganized at Covington, April 1, with the following officers: Dr. James B. Witherington, Munford, president; Dr. William H. Sale, Covington, vice-president, and Dr. B. V. Dickson, Covington, secretary and treasurer.

**Essex District (N. J.) Medical Society.**—At the annual meeting of this Society, held in Newark, April 1, Dr. James T. Wrightson was elected president; Dr. Walter S. Washington, vice-president; Dr. Archibald Mercer, secretary; Dr. Charles D.

Bennett, treasurer, and Dr. William S. Disbrow, reporter, all of Newark.

**Windham County (Conn.) Medical Society.**—The one hundred and ninth annual meeting of this Society was held at Willimantic, April 10. Dr. Frank H. Coops, Danielson, was elected president; Dr. Henry R. Lowe, Putnam, vice-president; Dr. James L. Gardner, Central Village, clerk, and Dr. Theodore R. Parker, Willimantic, county reporter.

**Steuben County (N. Y.) Medical Association.**—This Association was organized at Hornellsville, April 7, with the following officers: Dr. John G. Kelly, Hornellsville, president; Drs. Charles O. Green, Hornellsville, George C. McNeit, Bath, and Herbert B. Smith, Corning, vice-presidents, and Dr. Charles R. Phillips, Hornellsville, secretary and treasurer.

**Washington County (Texas) Medical Association.**—This organization, which was originally formed in 1868, was reorganized at Brenham, April 8, with the following officers: Dr. James T. Spann, Chappell Hill, president; Drs. R. H. Lennert, Brenham, and W. R. Campbell, Chappell Hill, vice-presidents, and Dr. John B. York, Brenham, secretary and treasurer.

**Florida Medical Association.**—The annual meeting of this Association was held in Tampa, April 9, 10 and 11. The following officers were elected: Dr. J. Harris Pierpont, Pensacola, president; Drs. Edward N. Liell, Jacksonville, and John MacDiarmid, Deland, vice-presidents, and Dr. J. D. Fernandez, Jacksonville, secretary and treasurer. St. Augustine was selected as the meeting-place for 1903.

**Broome County (N. Y.) Medical Association.**—This Association held its annual meeting in Binghamton, April 8, and elected Dr. Le Roy D. Farnham, president; Dr. William A. White, vice-president; Dr. Clarke W. Greene, secretary, and Dr. William H. Knapp, treasurer, all of Binghamton. Dr. John M. Farrington, Binghamton, was elected delegate to the State Medical Association, and Dr. Clarke W. Greene, alternate.

**Tidewater Medical Association.**—This Association, composed of colored physicians from Norfolk, Portsmouth, Suffolk, Yorktown, Gloucester, Hampton, Old Point, and Newport News, Va., was organized at Newport News, April 10, with the following officers: Dr. William R. Granger, Newport News, president; Dr. Philip L. Barber, Norfolk, vice-president; Dr. Welcome T. Jones, Newport News, secretary, and Dr. Thomas W. Addison, Hampton, treasurer.

**Fairfield County (Conn.) Medical Association.**—The one hundred and tenth annual meeting of this Association was held in Bridgeport, April 8. The newly-elected officers include Dr. Nathaniel E. Wordin, Bridgeport, president; Dr. William B. Cogswell, Stratford, vice-president; Dr. Harris F. Brownlee, Danbury, county reporter, and Dr. George S. Ford, Bridgeport, clerk. Delegates and alternates to the State Society were also elected.

**West Penn Hospital (Pittsburg) Resident Physicians' Association.**—This Association, composed of the resident physicians at the hospital for the past 28 years, held a smoker, April 10. About 40 physicians were present. The organization is a year old and the following officers were re-elected for another year: President, Dr. James W. MacFarlane; vice-president, Drs. Ellis E. Montgomery and Thomas L. Hazzard, Allegheny; secretary, Dr. J. M. Jackson, and treasurer, Dr. Elwood B. Haworth.

**Blue Earth County (Minn.) Medical Society.**—The reorganization of this Society was effected at Mankato, April 3, along the plans adopted by the American Medical Association. The following were elected officers: President, J. Francis Schefek; vice-presidents, F. D. Brandenburg, John Williams, and Julian A. Heilscher; treasurer, DeLos D. Smith; secretary, Carl J. Holman; judicial council, William Frisbie, Madge Timmerman-Holman and S. D. Sour. A resolution of approval of the plan of reorganization of the Minnesota Medical Society was passed. The subject of discussion for the evening was "Puerperal Fever, Its Prophylaxis and Treatment."

**Milwaukee County (Wis.) Medical Society.**—This Society held its annual meeting in Milwaukee, April 11. The following officers were elected for the ensuing year: Dr. Horace M. Brown, president; Dr. William H. Washburn, vice-president; Dr. Alfred W. Gray, secretary; Dr. Charles G. Willson, treasurer, and Drs. Alden B. Farnham, Ernest Copeland and Louis F. Frank, censors, all of Milwaukee. This Society was organized in 1846, and with the exception of two periods of inactivity, has been holding meetings regularly. At present it has more than eighty members, with the prospect that this number will be greatly increased.

**PHILADELPHIA COUNTY MEDICAL SOCIETY.***Regular Meeting, held March 26, 1902.*

President, Thomas H. Fenton, M.D., in the Chair.

**Symposium Upon Dysentery.**

DR. L. NAPOLEON BOSTON read a paper entitled "Amebic Dysentery with Hepatic Abscess; Rupture into the Lung; Amebæ Coli Found in the Sputum." Dr. Boston's paper recounted the case of a male, aged 21, who served for several months in the U. S. Army in the Philippines. Within the time of his service he several times had attacks of dysentery lasting 3 or 4 days. At one time, upon the day of admission to the army hospital, he had 28 bloody stools. There were hard nodular masses over the abdomen, with pain. The patient returned to the United States in June, 1901, and the symptoms abated. When seen by Dr. Boston in September, 1901, the lungs were normal. On Feb. 4, 1902, the patient was seized with chills, developing the symptoms and signs of a right lobar pneumonia. Respirations were 40, there was much pain. Drenching sweats followed, the temperature usually being 98 degrees. There was paroxysmal cough in the morning. Tenderness developed in the epigastrium. Impairment of resonance of the right lower lung occurred with crackling râles over the base. Girdle pain developed, and cough accompanied with free expectoration of blood-streaked gelatinous sputum. Microscopic examination of the sputum showed the presence of amebæ coli, oil globules, diplococci and blood cells; later there was presence of elastic tissue.

In a series of 2400 cases of amebic dysentery collected, 20 per cent. showed the development of hepatic abscess. The patient was shown in good condition, now manifesting no symptoms; the physical signs being practically nil.

DR. J. M. ANDERS directed attention to the afebrile state, a condition usual in such an hepato-pulmonary abscess. The speaker cited the case as an example of the common chronicity of the disease, symptoms being absent for months before its recent manifestation. The lesions were believed meanwhile to have persisted in the intestines.

DR. J. H. GIBBON referred to a man who had been in South Africa and upon whom he had operated for some condition causing enormous distension of the right hypochondrium. The diagnosis of a broken-down hydrated cyst of the liver was made. The liver extended below the umbilicus. The condition proved, upon operation, to be an amebic abscess with sterile pus. A sinus existed for three months subsequent to incision and drainage and then closed, the liver meanwhile contracting. There was no pain or leucocytosis.

**Bacillary Dysentery.**

DR. SIMON FLEXNER presented this subject and said that the classification of dysentery was formerly based upon its clinical and pathologic manifestations, but that its etiology is the only true basis of classification. According to pathologic findings, there were commonly said to be four forms, namely, catarrhal, diphtheritic, acute ulcerative and chronic ulcerative. As to the catarrhal form, there is nothing specific in its causation; it accompanies scarlet fever, diphtheria, tuberculosis, enteric fever, etc., and it is not at all likely that this form can ever have a specific etiology.

Another classification which has been common is endemic (chiefly in the tropics) and epidemic, acute in its nature. The two are not different, however, in their causation. Within the last several years the use of the microscope and culture tube has done much to put the classification upon an etiologic basis. The bacillary form of dysentery is found to be due to a bacillus not normally in the intestine. It is of the typhoid group, although different from the true typhoid bacillus. When a patient is infected with the bacillus, the blood undergoes such changes as to give the agglutination test with this special bacillus. This is particularly manifest in the form in which the pseudo-membrane is found in the intestine. Some three years ago this subject was studied by Shiga in Japan. Great difficulty was experienced because of the many organisms present in the intestine. The specific organism was differentiated by the agglutinative reaction. It has since been demonstrated by Strong and the speaker from studies in the Philippine Islands

and in Germany by Kruse; and Dr. Flexner said he had had the privilege of studying the disease in soldiers returned from Porto Rico. In this country the past summer there were sporadic cases and some epidemics. One of the latter occurred at Lancaster, Pa. One peculiar and striking fact is, that (especially in the diphtheritic form) when the bacilli diminish in number from the intestine, the reaction of agglutination lessens.

There is a group of cases in which the specific bacillus is never found; there is no agglutinative reaction and the disease is chronic. This is the amebic variety. In the acute form no amebæ are present. Ulceration in the two varieties also differs. The two forms are separated by clinical phenomena, pathologic findings, and especially in the micro-organisms causing them. We can not give true dysentery to the lower animals. We may cause lesions, but not characteristic ones.

It has long been noted that advanced Bright's disease and cirrhosis of the liver often end by dysentery. This form agrees exactly with the bacillary variety. The same organism is present. This is evidence of the wide distribution of this special bacillus, and the liability of debilitated subjects.

**Amebic Dysentery.**

DR. WILLIAM OSLER, Baltimore, addressed the society upon this subject. He stated that it was his fortune to have introduced the term. He briefly related experience with the disease in Johns Hopkins Hospital during the last 12 years. It is endemic in his city and state. Within the period mentioned 93 cases have been admitted to the wards; double this number had been treated at the dispensary. Four or five cases had come from the same locality. There were only 11 females in the group. The disease is more common among whites, there being only 9 colored patients of the number. It is a disease chiefly of young adults and is essentially chronic. Very few cases are acute. Fever is slight. Pus, mucus and blood are found in the stools. Four cases are under treatment at present, one of which has persisted for 6 years. It is common for constipation to alternate with diarrhea. Very few die of dysentery *per se*. Two cases died of perforation. Abscess of the liver is not infrequently a cause of death. Twenty-three cases developed liver abscess. Only the severe forms were admitted to the hospital.

After the studies of Shiga and Flexner it was thought that all forms of dysentery might be due to the bacillus of Shiga, but it is now known that there are marked differences between the bacillary and amebic forms. The amebic variety does not occur in widespread epidemics; it is rarely acute; it kills more by complications; its chronicity is marked, with a tendency to relapses; the amebæ coli or the pus of an abscess are found in the stools; the serum reaction of Shiga's bacillus is absent. This variety will be recognized to have distinct characteristics from the bacillary form. A considerable number of cases die. The mortality is greater than that of typhoid fever; it approximates that of pneumonia. Two cases of hepato-pulmonary abscess occurred at the hospital this winter. Operation in such cases is questionable. Of the cases in which abscess ruptures into the lung 40 to 50 per cent. get well without operation. Such a focus is often central at the root of the lung, can not be located, and is difficult of access. One of these two cases nearly strangled to death and finally died of exhaustion in his attempt to cough up the pus.

**The Treatment of Dysentery.**

DR. H. A. HARE claimed that much of the treatment commonly employed is based upon empiricism, and is irrational. The food should be easily digested and such as is chiefly digested in the stomach and duodenum, so that there will be but little residue to pass into the lower bowel. Milk is not always as useful as is supposed, because curds are apt to pass through the bowel undigested. Milk should be well diluted, better peptonized, and given in small quantities frequently. Solid food is contra-indicated. Soft eggs and milk toast may be taken.

The drug treatment is commonly one of three methods. First is the ipecac plan. Physicians believe they have found it beneficial, although its use is almost entirely empirical. There may be a rational basis in the fact that a profuse flow of bile

is caused. Sixty grains are given, vomiting resulting. Three grains are then given hourly until a profuse black stool is passed. Vomiting is controlled by opium and stimulants are freely used. The second is the purgative plan. Purgation is obtained by the free administration of magnesium sulphate. This is followed by aromatic sulphuric acid. The latter seems rational as bacteria may be destroyed by an acid medium or are at least rendered inert and the drug is astringent. The third plan is that of attempted intestinal antiseptics by bismuth salol, beta-naphthol, mercurials and other drugs. Mercurials at least have the value of increasing the flow of bile.

There seems to be no question as to the value of rectal injections of different kinds, if properly given. Potassium permanganate solution, 2 to 4 grains to the pint, has been so used and is believed to have controlled outbreaks of the disease. The speaker has used sulphocarbonate of zinc solution, 20 grains to the pint of water, and nitrate of silver solution in the same strength. In afebrile condition, with a tender abdomen, ice water injections are grateful. Intestinal lavage should be given very gently and slowly, at least 15 or 20 minutes being taken for the process. If there is much irritability of the bowel it is best to use two catheters, inserting one for the backward flow. Normal saline solution may be used with advantage as may also a solution of quinin which need not be strong as a solution of 1 to 5000 is deadly to the germ.

DR. JAMES TYSON said that his experience with the terminal dysentery of Bright's disease sustained the conclusions of Dr. Flexner. As to treatment, he had used every form except the ipecac method. He has most faith in the purgation method, associated with cold enemas and sufficient opium to quiet irritation.

DR. ALFRED STENGEL gave a plan of treatment which he had used with a happy result. Dr. Cunningham of India, one of the earliest writers upon amebic dysentery, had observed that when the feces were alkaline the conditions were favorable for the growth of the germ, but if the intestine were rendered acid the growth of the germ was inhibited. Upon this basis Dr. Stengel treated a young man who had had amebic dysentery for 4 or 5 years, by giving capsules of sulphur, 10 grains 3 or 4 times a day, guarded with opium. When the stools became acid, the amebæ disappeared and the stools became solid within 24 hours. The brother of this patient was given the same treatment with the same result.

DR. GIBBON asked Dr. Osler whether, in any of the Johns Hopkins cases, colostomy with through-and-through irrigation had been done.

DR. OSLER answered in the negative; he further stated that intestinal irrigation with quinin solution had been efficient; no motile amebæ were found after such a procedure. The speaker referred to the necessity, in colon irrigation, of giving, as Dr. Hare had pointed out, the injection very slowly, of having the hips raised, and of turning the patient from side to side during the procedure.

DR. FLEXNER stated that the outlook for serum-therapy in dysentery is not hopeful. A serum, to be effective in this disease, must probably be antibacterial in its effect. If the blood of apes could be used in the preparation of the serum the results would probably be better.

DR. HARE, in closing the discussion, emphasized the importance of clinically differentiating the forms of dysentery and thus being able to adopt the treatment suitable to the form present. As to the therapeutic use of sulphur, he believes that physicians will come back to its more frequent use; that in amebic dysentery it may have an antiseptic or other favorable effect upon the bowel besides the acid effect.

#### DETROIT MEDICAL SOCIETY.

*Meeting held March 26, 1902.*

##### Roentgen Rays in Epithelioma.

DR. H. R. VARNEY exhibited four patients and narrated their histories and the results of the x-ray treatment of the lupus, epithelioma and hypertrichosis previously existing in them. The cases follow:

CASE 1.—Lupus.—Miss F., general health fairly good except neurotic temperament. No history of tuberculosis in family.

In October, 1899, a purplish, hard, thickened nodule appeared on her left cheek and slowly increased in size. In a few months other lesions developed on the same cheek, involving about half its area during the first year of the disease. Constant treatment in 1900 and 1901 caused some improvement.

On Dec. 2, 1901, patient was referred to me by Dr. Steinbrecker and his diagnosis of lupus confirmed, it being serofuloderma ulcerosum, or tubercular gummata. The lesions, six in number, varied in size from a small five-cent piece to a dollar and were deep-seated. The exposures, begun December 2, were of five minutes' duration, four inches from a medium soft tube. No improvement noted until the sixth exposure, when there was a marked diminution in size of lesions and amount of discharge. On Jan. 10, the seventeenth exposure, erythema developed, due to the rays. Exposures were discontinued for ten days, during which time there was marked improvement; lesions became level with surrounding skin normal in color, infiltration and induration all carried away with no scar to mark location of the lesion. Patient had in all twenty-one exposures. Time of exposure from six to nine minutes, covering a period of about ten weeks.

CASE 2.—Epithelioma.—Mr. B., aged 59, old soldier, general health good, works every day. In June, 1900, he noticed a sore place on his nose, with scab constantly forming and falling off, having no tendency to heal. In August, 1900, Dr. McEachren made the diagnosis and cauterized at two different times. On Jan. 29, 1902, the growth being three-fourths of an inch long and a half-inch wide, daily exposures of six minutes' duration were started. The lesion was six inches from tube, other parts of the face being protected by a tin-foil mask. On February 18, erythema developed; exposures were continued, however. February 26, dermatitis noticed, exposures discontinued. March 10, lesion all healed. No crusts have formed since. Patient had in all twenty-six exposures covering three weeks and a half.

CASE 3.—Hypertrichosis.—Miss M. Both cheeks and chin were thickly covered with lanugo hair. When about the age of puberty, the length of the hairs worried her and she cut them with shears and pulled the coarser ones out until the condition became so embarrassing that she shunned all company. Dr. Biddle by electrolysis removed great numbers of the hairs.

Treatment with the rays began Nov. 18, 1901, for six minutes at first, increasing to nine minutes; exposing only the left side.

Patient's health and occupation prevented her from taking regular treatment. On January 17, the hair began falling from area which was first exposed. There has been no return of the hair on the left cheek and two months have elapsed since it fell out. The right side has had no exposures as yet. Thirty-six exposures have been given.

CASE 4.—Epithelioma.—Mr. A., typical growth on left cheek, in region of malar bone; of five years' duration.

He began treatment on March 4, 1902. From six minutes on that day the length of exposure was rapidly increased to twelve minutes. That length of time was through the next six treatments. Then dermatitis developed and the time was shortened to eight minutes. The reason for continuing the treatment, after dermatitis developed, was to carry away more of the rapidly disappearing waxy edges. March 21, exposures were discontinued. Sixteen exposures were given.

In the discussion there was brought out the necessity for careful observation of patients and compilation of results, that the foundation of x-ray therapy may be as accurate and reliable as possible for the future development of this promising branch of science.

#### NEW YORK OBSTETRICAL SOCIETY.

*Regular Meeting, held April 8, 1902.*

Dr. Malcolm McLean in the Chair.

##### Specimen of Ectopic Pregnancy (Tubal Abortion) with the Fetus in the Unruptured Membranes.

DR. HOWARD C. TAYLER presented this specimen. At the time of operation the right tube was found to be unruptured, its

outer end being distended and occupied by the fetal sac, which was partly in the tube and partly against the pelvic wall.

#### Retro-Peritoneal Echinococcus Cyst.

DR. TAYLER also presented this specimen and said that the history of the case went back to 1893 when Dr. Tuttle, at the Roosevelt Hospital, removed an echinococcus cyst of the omentum. Three months later Dr. I. Cragin operated upon an echinococcus cyst of the spleen; eight ounces of doughy cysts were evacuated by him and they continued to be discharged for several months later; subsequently the sinus closed and gave no further trouble. In 1901 the patient was again admitted and an echinococcus cyst was located behind the peritoneum and to the right of the rectum and was entirely independent of the uterus and its appendages. Six months after the last operation no trace of the disease could be noted.

#### Vesical Calculus from a Woman.

DR. EGBERT H. GRANDIN showed this specimen because of its extreme rarity; this was the second one he could recall. The first he saw three years ago and had, as its nucleus, a silkworm gut suture which had not been removed after the repair of a vesico-vaginal fistula. As a rule, in women, a foreign body of some kind is found as a nucleus of a calculus.

DR. MALCOLM MCLEAN said that it was a well-recognized fact that idiopathic calculi requiring removal by operation were rare, but the last woman he operated upon was such a one; there being no nucleus of foreign substance.

#### Specimens from Three Recent Cases of Early Ectopic Gestation.

DR. ABRAM BROTHERS presented these specimens. The first showed the fetus and ovum intact. In this case the chorionic villi had simply grown through and perforated the peritoneal coat of the tube and caused a fearful hemorrhage. The second specimen was an unruptured tubal pregnancy. The ovary removed with the tube did not show any corpus luteum, showing that the ovum was derived from the opposite ovary through transperitoneal migration. The third specimen showed the well-known form of ruptured tubal pregnancy. On the upper surface of the tube was a gash about one-half an inch long. The accompanying ovary showed very beautifully the corpus luteum. Dr. Brothers said he wished to accentuate the fact that the largest hemorrhages occurring in the early part of ectopic gestation may not come from a true rupture of the tube but from the outgrowth of the chorionic villi which are so vascular that when they have once penetrated the peritoneal coat they cause large hemorrhages.

DR. MCLEAN asked if some such hemorrhage could not come from the contiguous vessels of the tube.

DR. BANDLER said he had seen several cases where only two, three or six villi were found to have perforated the peritoneal covering; not only the ends of the villi but the placental sea, or intervillous space, was involved and thus enough blood entered the peritoneal cavity to produce symptoms of a profound intraperitoneal hemorrhage. Openings only microscopic in character may close and, after days or weeks, another perforation occur at the same, or at another, point.

#### Colon Bacillus Infection of the Female Genital and Urinary Systems.

DR. ALBERT H. ELY read this paper. He said that the virulence of the infection from the colon bacilli seems to be due to their associated pyogenic organisms, for we often find the colon bacilli present in large numbers in the urine without at times giving any symptoms. Again, when other pyogenic organisms have disappeared, the colon bacillus will remain as the organism which produced a most intractable type of disease; therefore he concluded that a suitable nidus was necessary for their propagation and action. Histories of three cases were narrated. The first showed the normal type of pelvic inflammation followed by evident colon infection, as shown by frequent cultures. The second and third cases illustrated the virulence and persistency of the colon bacilli infection, and how much more active these bacilli became when a suitable nidus for their propagation was afforded. He felt warranted

in deducing the following conclusions: 1. There exists as much necessity for thorough cleansing and rendering as aseptic as possible the rectum and colon, as the field of operation, especially when that operation is performed per vaginam. That in all cases of election the routine treatment of mild mercurial catharsis, followed by a saline and irrigation of the colon with salt or boracic acid, should be employed. 2. To reiterate a warning—the best results can be obtained when the intestines receive the minimum degree of trauma from handling and especially from the careless use of retractors, in cases where, for cosmetic effects or fear of hernia, too small incisions are made to permit of operation by sight rather than by touch.

DR. BROTHERS stated that he had had a series of pus cases in which, by microscopic examinations, colon bacilli were found in only the minority of the cases and he could not recall a single case in which the colon bacillus was the only bacteriologic element present.

DR. ELY was surprised at the remarks made by Dr. Brothers. The point he wished to bring out was, if colon bacilli are found, as reported by bacteriologists, even in arthritic joints, why did they vary so much in intensity and intractability.

#### TRI-STATE MEDICAL SOCIETY (IOWA, ILLINOIS AND MISSOURI).

*Proceedings of the Tenth Annual Meeting, held in Chicago, April 3 and 4, 1902.*

The Society convened at the Great Northern Hotel, under the Presidency of Dr. John C. Murphy of St. Louis, Mo.

#### Ligation of Arteries; Cocain Anesthesia.

DR. B. MERRILL RICKETTS, Cincinnati, Ohio, made a plea for a more general use of cocain for local anesthesia, especially in operations upon the head, neck and extremities. It is more efficacious, more desirable and less dangerous. It has a wide scope of usefulness, although as yet it had been applied to but a limited degree. Reference was made to its application to operations of any character on the extremities, and especially to its application of those involving the blood vessels. Cocain anesthesia would not only permit of the ligation of the more important blood vessels, but celiotomy for various purposes as well. The removal of various neoplasms, malignant and benign, plastic operations upon nerves, cutaneous, muscular and bony structures in a healthy or pathologic state, removal of foreign bodies, or amputation of any part of the upper or lower extremities were advised under cocain anesthesia. Amputation at the shoulder-joint had been successfully accomplished with cocain as a local anesthetic by Crile and, while there was no recorded case for demonstration, there was no reason why amputation at the hip-joint should not now be accomplished in this manner. Resection of ribs and amputation of the breasts should be more frequently done under cocain. Dr. Ricketts advised a 0.5 to 1.5 per cent. solution, and said that an amount of solution containing from 0.5 to 1.5 grains of cocain need not be exceeded in performing any operation.

The great advantage of this method of anesthesia is its freedom from any danger, if it is properly used, and it can be thus applied, which is more than can be said of ether, chloroform, nitrous oxid or any of their combinations. Nausea, vomiting, cephalalgia, nephritis, bronchitis, pneumonia and shock are absolutely avoided.

DR. H. A. LEIPZIGER, Burlington, Iowa, did not believe any surgical operation nowadays was a minor matter. Since the acceptance of bacteriologic factors and the danger attending all surgical procedures, he believed the word minor should be entirely dropped.

DR. FLAVEL B. TIFFANY, Kansas City, Mo., had had some experience in the use of cocain in ophthalmologic operations. He almost always adds adrenalin to the solution and then no hemorrhage results. He had never had bad results from its use, except when he had employed it on mucous membranes.

DR. HAROLD N. MOYER, Chicago, said that the question of cocain as a local anesthetic was still *sub judice*, and, person-

ally, he would prefer to take his chances in the hands of a good anesthetist with chloroform or ether rather than have cocaine injected into his spinal cord. He thought the infiltration method of Schleich had been disappointing in many respects, in part due to difficulties in sterilization.

DR. RICKETTS, in closing the discussion, condemned spinal anesthesia, saying that he had never had the courage to resort to it. As to the use of adrenalin, there were some advantages to be obtained from combining it with cocaine.

#### Technique and Possibilities of Endo-Vesical Operative Procedures.

DR. LOUIS E. SCHMIDT, Chicago, mentioned the important points in connection with operative cystoscopes and showed their differences.

1. *Nitze Operative Cystoscope.* Here the lamp, prism and window are on the concave surface of the beak. In front of the space between the lamp and the window the operative appliances are placed. The operative appliance carries in its hollow shaft the optical apparatus. The latter is movable, so that the operative appliance can be brought to different distances and positions from the cystoscope part. These mechanical appliances are the galvano-caustic snare, cautery, small forceps and lithotriptic forceps.

2. *The Casper Operative Cystoscope* differs from the Nitze instrument in that the lamp, window and prism are on the same plane, so that the whole optical apparatus is straight. The operative part is practically similar to the Nitze. Both of these cystoscopes compel the operator to work under indirect vision.

3. *With the Kolischer Operative Cystoscope* the operator works under direct vision. The lamp and window are situated on the convexity of the beak. To the under part of the cystoscope is attached a canal through which the different instruments are introduced into the viscous. Their working end appears just below and in front of the window.

#### Prenatal Syphilis.

DR. OHLMANN-DUMESNIL, St. Louis, Mo., detailed a case of prenatal syphilis. He condemned the use of the terms hereditary or congenital syphilis. He prefers to use the word prenatal, believing that it is more comprehensive and more clearly defines the condition which exists.

#### Sporadic Infantile Myxedema Resulting in a Cretinoid Condition.

DR. JAMES FREDERICK CLARKE, Fairfield, Iowa, reported a case. The patient, aged 20 when first seen, a marked imbecile of typical cretinoid condition, with a negative family history. The degeneration began at the end of the first year, and was shown by a series of photographs taken every few years through life. Thyroid feeding for the nine months to date showed an increase of two and three-quarter inches in height and a marked transformation as to intelligence and physiognomy. This was illustrated by a series of photographs, taken every two months during treatment. The patient has been taking thyroid tablets in dosage equal to 60 grains of fresh gland every day.

DR. FRANK P. NOBURY, Jacksonville, Ill., said that a boy, aged 9, seen by him in consultation, was fed on thyroidin and the result was satisfactory and pleasing. He said the results of thyroid feeding had been satisfactory in the treatment of such cases.

#### Pathologic Specimens.

DR. ISAAC A. ABT, Chicago, exhibited some interesting pathologic specimens, including a specimen of diaphragmatic hernia from an infant; a glioma of the cerebellum of the right side from a child of 6 years; intussusception from a marantic baby of 21 months; a picture of the brain and spinal cord from a case of epidemic cerebellar spinal meningitis; adenoma of the liver from a 21-month-old baby, and a photograph showing the location of a spina bilida during life.

#### Cholecystectomy versus Removal of the Mucous Membrane of the Gall-Bladder.

DR. EMIL RIES, Chicago, presented this paper, confining his remarks to two methods, cholecystostomy and cholecystectomy, the former being a method, practiced by Kehr and Mayo, of

stitching a rubber tube into the contracted gall-bladder and making the joint water-tight by a suture around the rubber tube. As an emergency operation, cholecystostomy is satisfactory, but it is not an ideal method. An operation to be compared with cholecystectomy was Mayo's operation of removal of the entire mucous membrane of the gall-bladder and leaving the gall-bladder in place. While this operation seems very reasonable and had been performed by Mayo and others with success, the author considered it open to serious objections. He then reported a patient who had been troubled with gall-stones for 27 years upon whom he operated three months ago, removing a small contracted gall-bladder.

#### Plastic Surgery in Ophthalmology.

DR. F. B. TIFFANY, Kansas City, Mo., spoke of the use of large skin grafts, to restore lids destroyed by lupus, burns, cancer, etc., taken from remote parts without a pedicle. These grafts embrace the entire skin, are transplanted directly without being passed through any medium, and are put upon a granular surface where they grow without sloughing.

In cases of distichiasis and trichiasis that have been previously operated on and there is no integument to spare, von Milligan's operation is recommended, which consists in splitting the edge of the lid at the mucous line and transplanting a strip of mucous membrane from the lip of the patient, vagina, or from the conjunctiva of a rabbit's eye. In ordinary cases of entropion he uses the electro-cautery, incising the integument near the margin of the lid from one canthus to the other two or three millimeters distant from the margin of the lid; then, from cicatrization the margin of the lid is turned away, correcting the entropion. For ectropion he makes a similar operation, cutting with the electro-cautery the conjunctiva from near the punctum of the outer canthus at a distance of two or three millimeters from the margin of the lid. Sometimes he makes two or three longitudinal incisions. If more than one or two, a third is made at the retrotarsal fold or eulde-sac. Probably 95 per cent. of all cases that have come to his clinic and private practice of entropion and ectropion within the last three years have been corrected by electro-cautery treatment.

For congenital ptosis, where there is absence of the levator palpebrae superioris, he makes Panas' operation, which gives better results than any other operation that has ever been made up to the present time. The steps of this operation were described and pictures presented of a boy, aged 10, with complete congenital ptosis, in whom there was the absence of the levator palpebrae superioris of each lid. The result was excellent, as shown by the photograph taken subsequent to the operation.

#### Differential Diagnosis of Smallpox.

DR. J. C. SULLIVAN, Cairo, Ill., emphasized the point that whenever a patient complains of severe and persistent backache, followed by fever and a pustular eruption affecting the palms of the hands and the soles of the feet, protruding from beneath the outer skin, there is a case of smallpox to deal with, no matter how insignificant or mild it may appear, and confluent or even hemorrhagic smallpox may be contracted from it. Hence the necessity of immediate vaccination of all parties exposed and of strict quarantine or isolation in each case. There are but two diseases that produce these phenomena, namely, syphilis and smallpox. The former should not be confounded with the latter, as a history of chancre would suffice for the differentiation. From measles it may be differentiated by Koplik's sign, when found, which consists in the appearance of little white pearly bodies on the inside of each cheek before the faucial redness of early measles. The typical lobster rash, strawberry tongue and persistent white line of that most eccentric of all diseases proclaims scarlet fever; a multiform punctated and individual crescentic rash, r  theln; the successive crops of vesicles affecting the shoulder-blade, probably chicken-pox. A pustule stuck on the surface of the skin, impetigo, lichen planus and papular eczema may be at first confounded with smallpox; but the pustular eruption of the palms of the hands and soles of the feet makes the diagnosis of smallpox positive. The essayist did not believe there

was such a disease as Cuban or Porto Rican itch. The adherents of the theory of a third or intermediate disease similar to r  theln, measles and scarlet fever have strongly fought the idea that modified smallpox could be a true disease, but by repeated examinations and diagnoses the most eminent specialists have named it smallpox. Many admit its contagiousness, but fail to quarantine. In this respect they err, for when a disease, no matter what its name or nature, is contagious, it is the duty of every physician before it becomes endemic or epidemic, to report it to the health authorities and work in concert with them to see that it is at once quarantined until all danger of its communication to others shall have passed.

#### **Conglomerated Cystic Kidney.**

DR. J. F. HERRICK, Ottumwa, Iowa, narrated a case of conglomerated cystic kidney and gave the autopsy findings.

#### **Ligation of Common Iliac or of External and Internal Iliacs Preliminary to Amputation of Lower Extremity at Hip-Joint.**

DR. AUGUSTUS C. BERNAYS, St. Louis, Mo., said that in many cases Senn's and Wyeth's methods left much to be desired, if it seemed necessary to save the patient from even a small loss of blood. He reported an operation and presented photographs of a case of myxosarcoma of the thigh reaching above Poupert's ligament, in which the ligation of the common iliac enabled him to perform an almost absolutely bloodless operation. The ligation was done through a small abdominal incision made exactly over the brim of the pelvis on the affected side. Dr. Bernays claimed that the aseptic ligation of the iliacs could in no way add to, but would probably lower, the percentage of mortality in those cases in which the ablation of the lower extremity was indicated. He strongly recommended the method in suitable cases. His case recovered in a few weeks.

#### **Hemorrhage After Tonsillotomy.**

DR. H. A. LEIPZIGER, Burlington, Iowa, said that tonsillotomy is one of the so-called minor operations, but one which becomes very formidable in case of hemorrhage. Even if there is no fatality, the apparent danger, continuance of bleeding and frequently the inability of the surgeon to arrest the same, create a degree of anxiety for doctor and patient, and a liability to censure and reproach for the doctor alone which should stimulate all surgeons to cease regarding the operation as minor. The patient should be informed of the dangers and examined before operation at least as carefully as before a life insurance examination, which never involves more than a limited amount of money. The operation should never be done in the physician's office, but by preference in a well-appointed hospital. Bleeding will follow a tonsillotomy as well as a knife. The commonly advised styptics and methods of arresting the bleeding do so when the bleeding is insignificant; when it is severe they all fail. Even tying the common carotid has failed. There seems to be underlying the parenchymatous oozing some nervous or vasomotor influence which is excluded by syncope or unconsciousness. The latter is obtained by hypodermics of morphia, which were used in the writer's case with sufficient effect to make him believe it arrested the bleeding when all other means had failed.

#### **Psychology as Applied to Modern Medicine.**

DR. G. H. EISKEMP, Washington, Iowa, read a paper with this title, referring to the delusions under which a large number of people are laboring. The sudden rise and rapid spread of the religious vagaries and scientific absurdities taught by Eddy, Dowie, Schlatter, Schweinfurth and others form curious chapters in the mental history of our age. How to counteract these modern unwholesome tendencies is the question. Criticism will not do it. Ridicule will not suffice. Such movements are strengthened by denunciation. They fatten on persecution. He thought the death-blow to all such scientific, philosophic and religious vagaries was struck when the truth was shown concealed behind the fallacy. It is at this point that medicine has failed in the performance of her duty. While Eddyism has swung to one extreme, medicine has swung to the other. If the followers of Mrs. Eddy had laid sole emphasis on the psychic, ignoring the physical, the physician, on

the other hand, was tempted to confine himself to the physical, leaving out of account the mental. Had physicians studied the psychic side of life as they ought, applying psychologic principles to the treatment of disease, there could be no reasonable doubt that much could have been done to counteract these delusions. Why should the physician leave this interesting and important field to the untrained quack to make of it a matter of merchandise? That many human ailments are of mental origin and can be healed by purely psychologic means, there can be no question. Into many others the psychic entered as a very important element. This being so, in order to successfully treat the human body, one must know something of the human mind, its laws and methods of working. Without this knowledge, accurate diagnosis of disease, in some instances, is impossible. When carefully diagnosed, it might turn out that the patient needed the good offices of a clergyman, a psychologist, or a neurologist. At all events, the physician must be able to make the diagnosis, whoever effects the cure.

Man was something more than a bundle of nerve cells, bones, blood vessels and various kinds of tissue. Therefore, the successful practitioner must interest himself in something besides physical symptoms and matters of organic function. So long as man is made of body and mind, so long as these continue to influence one another, just so long will the study of the psychic side of human nature be a valuable part of the equipment of him who ministers successfully to its physical side. That a new emphasis would be put upon the psychologic element in the future, the author had every reason to believe. It was his firm conviction, arising from a conception of the profound need of such investigation, that the time was ripe for a forward move in this direction.

*(To be continued.)*

### **Medicolegal.**

#### **South Dakota Statute Compliance with Law Presumed.**

—In the case of Webster vs. Lamb, an action brought to recover for professional services, to which a general demurrer was interposed, the Supreme Court of South Dakota says that it was not necessary to allege in express terms that the party suing had obtained a license from the board of health and had duly recorded the same. It therefore affirms an order overruling the demurrer. It says that the general presumption that every man is innocent of crime renders it unnecessary, in a civil action, to plead or prove compliance with statutes of this character, and a sued party desiring to put the point in issue must do so by way of answer.

#### **Cause of First Fracture that Also of Rebreaking Leg.**

In the personal injury case of the Postal Telegraph Cable Company vs. Hulsey, as it is now entitled, but which was brought by the latter party, it appeared that during the time he was confined to his bed from his broken leg and was not able to sit up, he had something like colic one night, accompanied with vomiting; that he went to turn over on his side, to keep from vomiting on his bed, and felt something like a sting in his thigh. The evidence tended to show that at that time the leg was rebroken, or the fracture disunited after it had begun to unite. There was no pretension that the leg was rebroken by any conscious fault of his. Under these circumstances, the Supreme Court of Alabama holds that, if the leg was rebroken, it was a natural result, or one liable to happen from the cause of its being broken in the first instance, having immediate and causal connection therewith. But for the original breaking, it says, the rebreaking could not have occurred.

**Examinations Made by Experts for State.**—In the homicide case of the State of Connecticut vs. Rathbun complaint was made of the refusal of the trial judge to give the jury an instruction framed for the evident purpose of discrediting the evidence of the state concerning the results of certain chemical and medical examinations. The requested instruction was to the effect that such evidence, being of examinations made not in the presence of a representative of the accused, should be carefully considered in view of the possibility of a failure to

seek for or develop facts and conditions to the advantage of the accused which an impartial and complete investigation would have disclosed. Such instructions, involving an insinuation, if not assumption, that the examinations in question were not impartial or complete, the Supreme Court of Errors of Connecticut holds, the accused was clearly not entitled to have. The judge, it says, told the jury to give all the evidence calm and conscientious consideration. There is no rule of law which compelled him to single out this particular evidence of the state for special caution as evidence coming from a tainted source, as in the case of the evidence of an accomplice.

**Entitled to Hearing Before Board of Health Itself.**—A New Jersey law requires the consent of the municipal authorities and local board of health to the location or enlargement of any cemetery, and provides that in case of the refusal of the municipal authorities and local board of health to grant such consent, application may be made to the state board of health. Under this provision, if the municipal authorities consent, and the local board of health refuses to grant permission to the location of a cemetery within the municipality, the Supreme Court of New Jersey holds, in the case of *State (Dodd and others, Prosecutors) vs. State Board of Health*, that this is a refusal to grant consent, within the meaning of the act, and application may be made to the state board of health to reverse such action of the local authorities. But what is of still more general interest, the court holds that, in hearing an application in such a case, the state board of health acts judicially, and persons interested have a right to be heard before that board. For example, in this case, when the application to locate a cemetery was presented to the state board of health, it was referred to the standing committee on cemeteries, burial, and transportation of the dead, for investigation and report. That committee consisted of the president of the board, ex officio, and two other members. An investigation of the site of the proposed cemetery was made by the medical inspector of the board and one of the members of the committee, and the result of the examination submitted to the board by the medical inspector, and a hearing given by the same committee. At that hearing two members were present. The committee seems to have made a report to the board, but no other hearing was actually held by the board itself. The court says that the board of health was acting judicially upon the application before it, and all who were interested in that application were entitled to be heard by the board in a legally organized meeting of the board. The delegation to a committee to examine and report upon facts was within the power of the board, but the parties were entitled to be heard by the board upon the significance of those facts, and the legal questions which the situation gave rise to. The prosecutors were freeholders and taxpayers in the township, and, as such, were entitled to be heard before the state board of health. Because no proper hearing was given, the court sets aside the action of the state board of health in the case.

**Salicylic Acid in Fruit Syrup Under Pure Food Law.**—The Supreme Court of Pennsylvania says, in the case of *Commonwealth vs. Kevin*, that the purpose of the "Pure Food Law" of that state was to prevent the adulteration of food, the term "food" including all articles used for food or drink by man. In case of food, an article shall be deemed to be adulterated within the meaning of this act, for one thing, it is provided therein, "if it contains any added substance or ingredient which is poisonous or injurious to health." Here, however, where the prosecution was for selling raspberry syrup containing salicylic acid, it was contended that, if the jury should find from the evidence that the single bottle actually sold did not contain salicylic acid in sufficient quantities to be poisonous, or injurious to health, there should be an acquittal. But the Supreme Court does not adopt that construction of the law. It says that it is not a poisonous or injurious compound resulting from the addition of a foreign ingredient that the clause quoted declares to be an adulterated article. The terms of the clause declare against a compound that is formed by the addition of a poisonous or injurious ingredient. The guilt of the accused, therefore, did not depend upon the nature or character of the compound resulting from the addition of the salicylic acid to

the fruit syrup, but was to be determined solely upon the poisonous or injurious qualities of the acid which was the ingredient added to the food. And the court affirms a judgment of conviction. Nor does it consider that the above clause offends against any provision of the constitution of the commonwealth. It says that it does not prevent the admixture of pure articles as a food, nor prohibit the addition of a healthful ingredient as a fruit preservative. It is directed against the introduction into a food product of a substance foreign to it, and of a poison-out or injurious nature. The evidence in the case would justify no other conclusion than that salicylic acid is poisonous and injurious to the human system.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Hyperemia of the Conjunctiva.

Drs. Wood and Woodruff, in *Med. Standard*, recommend the following treatment of hyperemia of the conjunctiva: Remove the cause if possible and apply cold locally to the closed eyelids three or four times a day. In a few cases hot water is more effective than cold water. Following the application of cold or hot water, several drops of a soothing, non-irritating solution should be instilled into the conjunctival sac as follows:

|                            |     |    |
|----------------------------|-----|----|
| R. Acidi borici .....      | 3ss | 2  |
| Sodii biboratis .....      | 3ss | 2  |
| Aquæ rosæ .....            | 3ii | 8  |
| Aq. destil. q. s. ad. .... | 3ii | 60 |

M. Sig.: Instill locally into the eye.

If the lids are gummy or show a tendency to adhere in the morning a little simple ointment should be gently rubbed on the eyelashes at night. Sometimes a more stimulating lotion is desired, as follows:

|                      |          |       |
|----------------------|----------|-------|
| R. Zinci sulph. .... | gr. i-ii | 06-12 |
| Aq. destil. ....     | 3i       | 30    |

M. Sig.: Apply locally once or twice daily.

In the same journal they advise the following in the treatment of ophthalmia neonatorum:

|                          |       |    |
|--------------------------|-------|----|
| R. Hydrastin sulph. .... | gr. v | 30 |
| Acidi boracici .....     | gr. v | 30 |
| Sodii biboratis .....    | gr. v | 30 |
| Tinct. opii .....        | 3ss   | 2  |
| Aq. destil. ....         | 3i    | 30 |

M. Sig.: To be instilled into the eye every hour.

Other solutions may be used as follows:

|                                 |       |     |
|---------------------------------|-------|-----|
| R. Potassii permanganatis ..... | gr. i | 06  |
| Aquæ destil. ....               | 3viii | 240 |

M. Sig.: To be dropped into the eye once or twice a day; or:

|                              |        |     |
|------------------------------|--------|-----|
| R. Hydrarg. bichloridi ..... | gr. ss | 03  |
| Aquæ destil. ....            | 3viii  | 240 |

M. Sig.: Drop into the eye daily.

According to them, chlorin water is very efficient when much pus is secreted:

|                      |      |     |
|----------------------|------|-----|
| R. Aquæ chlori ..... | 3vi  | 25  |
| Aq. destil. ....     | O. i | 480 |

M. Sig.: Apply locally.

### Cuprol in Conjunctivitis.

According to von Sicherer, as stated in *Ther. Month.*, cuprol is a new remedy employed in the treatment of conjunctivitis which he claims has proven to be of great value in numerous cases treated by him. Cuprol represents an organic combination of copper and nucleic acid and contains about six per cent. of copper. It is readily soluble in water, especially in hot water, and forms a clear solution, even with albuminous substances, producing no coagulation. In the presence of alkalies no precipitate takes place. He employs a 10 per cent. solution prepared in warm water. He states the following principal ad-

vantages of this preparation over the other organic preparations of copper: 1. A 10 per cent. solution causes no pain or only very slight pain. 2. The tissues are but slightly irritated. He employs the remedy chiefly in cases of acute and chronic catarrhal conjunctivitis, but it may also be employed in the treatment of phlyctenular conjunctivitis.

#### Uncontrollable Vomiting.

The following outline of treatment is recommended by *Jour. de Med. de Paris* for checking persistent vomiting in pregnancy or from other causes:

|   |          |     |
|---|----------|-----|
| R. Cocainæ hydrochlor. ....                   | gr. ii   | 10  |
| Antipyrin .....                               | gr. xv   | 1   |
| Aq. destil. q. s. ad. ....                    | ℥iiss    | 100 |
| M. Sig.: One teaspoonful every half hour; or: |          |     |
| R. Cocainæ hydrochlor. ....                   | gr. viii | 5   |
| Aquæ destil. ....                             | ℥iiss    | 6   |

M. Sig.: Six drops, repeat in one hour, then in three hours; after this three or four drops before each meal.

As a local application to the cervix in vomiting of pregnancy or acute metritis:

|                                 |        |    |
|---------------------------------|--------|----|
| R. Cocainæ hydrochloratis. .... | gr. xv | 1  |
| Ext. belladonnæ .....           | gr. iv | 25 |
| Vaselinæ .....                  | ℥iiss  | 75 |

M. Sig.: Apply locally once a day on a tampon.

#### Suppurating Wounds.

Schwarz, in *New York Med. Jour.*, recommends the following as a local application in suppurating wounds:

|                          |     |   |
|--------------------------|-----|---|
| R. Pulv. iodoformi       |     |   |
| Salol                    |     |   |
| Bismuthi subnit.         |     |   |
| Pulv. charcoal           |     |   |
| Pulv. cinchonæ           |     |   |
| Pulv. benzoini, āā ..... | ℥ii | 8 |

M. Sig.: Apply locally once daily.

#### Quinin as a Dressing.

J. Read, according to the *Med. News*, recommends a mixture of quinin and cod-liver oil in the treatment of various skin troubles, combined as follows:

|                            |       |     |
|----------------------------|-------|-----|
| R. Quininæ sulphatis ..... | ℥i    | 4   |
| Olei morrhuæ .....         | ℥viii | 240 |

M. Sig.: Shake well and apply locally.

He employs it in the treatment of tertiary and rheumatic ulcers of the leg, gangrene of the skin, burns in which large surfaces have sloughed away. He states that it has the advantage of supplying the system with an oily food and a tonic drug.

#### AS A WASH IN TREATMENT OF CHANCROID.

|                           |        |    |
|---------------------------|--------|----|
| R. Creosoti .....         | m. iii | 20 |
| Hydrarg. bichloridi ..... | gr. iv | 25 |
| Glycerini .....           | ℥ii    | 60 |
| Aquæ rosæ .....           | ℥iii   | 90 |

M. Sig.: Apply frequently as a wash.

#### To Relieve Tympanites.

The following is of great service to relieve the distress caused by gas collecting in the lower bowel:

|                            |       |     |
|----------------------------|-------|-----|
| R. Mag. sulph. ....        | ℥ii   | 60  |
| Spts. terebinthinæ .....   | ℥i    | 4   |
| Tinct. asafoetidæ .....    | ℥iiss | 45  |
| Mucilag. acaciæ .....      | ℥ii   | 60  |
| Aq. destil. q. s. ad. .... | ℥i    | 480 |

M. Sig.: As an injection by a high rectal tube.

#### Scarlet Fever.

Ames, in *Phys. and Surgeon*, emphasizes the following points in the eradication of scarlet fever: 1. Every suspected case of scarlet fever should be isolated until a conclusion is reached. 2. The family should be instructed to maintain isolation until all signs of peeling have disappeared. 3. All members of the family who desire to leave the house, should do so on the first day after their clothing has been disinfected by exposure to formaldehyd gas for six hours. 4. The attending physician should have as little contact with the patient as possible; cleanse his hands thoroughly with a bichlorid solution and disinfect his clothing. He states that formaldehyd, ten ounces to 1000 cubic feet, will destroy all germs.

#### For the Itching in Scarlet Fever.

The following combination is recommended to relieve the itching in scarlet fever:

|                              |     |    |
|------------------------------|-----|----|
| R. Ung. picis liq. ....      | ℥i  | 4  |
| Ung. zinci oxidi .....       | ℥ss | 15 |
| Vaselinæ albi q. s. ad. .... | ℥ii | 60 |

M. Sig.: Apply locally once or twice a day.

#### Neuralgia of the Fifth Nerve.

Barber, as noted by *Amer. Med.*, states that he effected a cure of trifacial neuralgia of three years' duration by the administration of one granule, containing 1/10 of a milligram of aconitin, every four hours for three days, followed by:

|                             |            |  |
|-----------------------------|------------|--|
| R. Ferri sulphatis (exsic.) |            |  |
| Ext. anthemidis, āā .....   | gr. viiiss |  |

M. Ft. pil. No. ii. Sig.: Two such pills daily for two weeks.

#### As an Antineuralgic Ointment.

Menier, according to the *New York Med. Jour.*, recommends the following formula as a local application in the treatment of the different forms of neuralgia:

|                          |      |    |
|--------------------------|------|----|
| R. Pulv. opii .....      | ℥ss  | 2  |
| Ext. belladonnæ .....    |      |    |
| Liq. petrolati, āā ..... | ℥iii | 12 |

M. Sig.: Rub in thrice daily, continuing the frictions for five or ten minutes at each application.

#### Local Treatment of Rheumatic Arthritis.

|                             |      |     |
|-----------------------------|------|-----|
| R. Methyl salicylatis ..... | ℥iii | 12  |
| Spts. chloroformi .....     | ℥ii  | 8   |
| Menthol .....               | ℥ss  | 2   |
| Lanolini .....              | ℥iv  | 120 |

M. Sig.: Apply locally to the affected joint night and morning.

#### General Toxemia.

Shelton, in *Clinical Rev.*, recommends as the most efficient measure in the treatment of those poisons generated in the alimentary canal, the following:

|                          |        |    |
|--------------------------|--------|----|
| R. Fel bovis (oxgall)    |        |    |
| Guaiacol carb., āā ..... | gr. ii | 12 |

M. Ft. cap. No. i. Sig.: One such capsule before each meal;

or:

|                       |        |    |
|-----------------------|--------|----|
| R. Fel bovis (oxgall) |        |    |
| Benzonaphthol         |        |    |
| Pancreatin, āā .....  | gr. ii | 12 |

M. Ft. cap. No. i. Sig.: One such capsule before each meal.

#### Worms.

According to Scholl, in *Jour. Med. and Surgery*, the best treatment for expelling worms is santonin, which is prescribed probably more than any other drug. He recommends that it be given in powder form on bread and butter or in the form of lozenges; and sometimes he combines it with calomel. He states that it is destructive to both the thread and round worms and their ova. He always combines or follows the administration of the santonin with a purgative, as it assists in the expulsion of the worms and ova. The best plan is to give the anthelmintic at night and follow with the laxative the following morning. Overdoses should not be given.

#### Bursæ of the Knee.

Bjorkman, in *Merck's Archives*, recommends the following local applications in the treatment of bursæ of the knee where surgery can not be employed:

|                         |    |    |
|-------------------------|----|----|
| R. Ichthyoli .....      | ℥i | 4  |
| Ung. kalii iodati ..... | ℥i | 30 |

M. Ft. Unguentum. Sig.: Rub in well three times daily;

or:

|                         |         |    |
|-------------------------|---------|----|
| R. Ichthyoli .....      | ℥i      | 4  |
| Olei ricini .....       | ℥ss     | 2  |
| Spts. etheris .....     | gr. xlv | 3  |
| Acidi salicylici .....  | gr. xv  | 1  |
| Collodii q. s. ad. .... | ℥iiss   | 45 |

M. Sig.: Apply with a small brush once or twice a day.

#### Indications for the Use of Phosphoric Acid.

Martinet, as quoted by *Ther. Month.*, describes a number of cases to support his statement that hypo-acidity of the urine, accompanied by an abnormally large amount of phosphates, is

frequently the index of hyperchloridia in the stomach. On the other hand, hyperacidity of the urine and a small proportion of phosphates suggest hypo-acidity in the stomach, with hypo-acid dyspepsia, stasis of the food, acid fermentation, etc. In such cases, he states, the administration of phosphoric acid may promote digestion and check the acid fermentations by its eupeptic and antiseptic action.

1. **State Care of the Insane.**—Morton's paper covers the general subject of treatment of the insane, favoring state care to a certain extent, holding that many cases, however, can be cared for at home. On account of the prejudice against public institutions, he advises the sending of patients that can not be cared for at home to private institutions at first. He does not think that the asylum physician should have more than 50 patients to care for and does not favor the bed treatment as especially necessary. He is conservative in regard to the use of hypnotics and sedatives.

3. **Tropical Diseases.**—Egan comments upon the high death rate in the tropics and describes the striking neglect of ordinary sanitary precautions in Porto Rico. The death rate in that island has been about twice the birth rate and is largely attrib-

uted by the author to the neglect of sanitation. The two greatest causes of death are anemia and tuberculosis, the former twice as common as the latter, and he doubts the importance of ankylostoma as a factor in its production. He finds the parasites present in a very large percentage of all patients. He says that if Porto Rico were not naturally one of the most healthy countries in the world all the people would have been dead long since from one cause or another. Concerning venereal disease in the army he approves of the British plan of depriving a soldier of his pay for every day that his services are lost to the government through his immorality. Only a certain proportion of the cases really require hospital treatment, and yet all who are ordered to hospital by the line officers—sometimes through syphilophobia—must go. He speaks particularly of the handicap the army surgeon has in having orders carried out if the line officers in command do not choose. He thinks a reform is necessary in this regard and claims that the proportion of venereal cases in hospital, which sometimes is 20 per cent., could be reduced to 1 or 2 per cent. by discharging those for whom the only necessity is that they report regularly for medicine and dressing.

4. **The Mammary Gland in Primiparae.**—After describing the anatomy and physiology of the gland, Bannan mentions the hygienic treatment before delivery, and insists on its importance. She believes mothers should nurse their children and says that it has a healthful reflex influence. In the treatment of cracked nipples, if only one is affected it should be relieved of its duty; if both are affected a compromise system should be followed, and only the one least affected used. Massage and bandaging is the most satisfactory treatment. The importance of the breast binder in primiparae is emphasized. Whatever principles of surgery are thus outraged, it is better than suspending the function altogether and trusting the babe to the doubtful issue of artificial feeding.

5. **Pelvic Deformities.**—Ayers' paper takes up the question of what shall be done in such deformities as will prevent the birth of a living child. He says that when the deformity leads to the employment of version, forceps or craniotomy, a large percentage of still births is the result. Cesarean section and symphysiotomy are discussed and he insists on the greater ease and security of proper preparation for symphysiotomy in the ordinary surroundings and says: "In considering this operation, I do not refer either to the suprapubic and postpubic Italian method of operating, or to the open anterior French method, but to my subcutaneous method heretofore described. In order to secure thoroughly satisfactory conditions for operation, the following are needed: A scalpel, bistoury, steel male urethral sound, a soft-rubber retention catheter, two china wash-bowls, forceps, absorbent cotton, adhesive plaster, and clean hands of at least one individual—the operator. No needles, sutures, sterilized cloths, or dressings are required. The genital region is washed with soap and water, then with bichlorid solution. The instruments are placed in a solution of either carbolic acid or lysol. The urethra is held to one side, the symphysis severed by introducing the bistoury under the clitoris upon the face of the joint, as heretofore described, while hemorrhage is prevented by pressing a wet wad of cotton on the small opening. The child is delivered with the forceps, the after-birth removed, the catheter inserted (after bringing the pubic bones together), the wings of the pelvis are strapped with adhesive plaster, and the wound completely closed by bringing the knees together and binding them. In the after-treatment, such a sling as Dickinson's can be readily set up, if my hammock-bed is not available. The manipulations which may have preceded this operation need not affect its results, as the wound is above the vaginal orifice and away from its discharges. In one of my cases, in which infection of the genital tract followed a sloughing of the posterior vaginal wall from an old cicatrix, the joint wound healed by first intention." The recent greatly improved results in Cesarean section are due not only to improved method but to early performance; he points out, however, that the mortality in late years is greater than in symphysiotomy. There are probably many more craniotomies being performed to-day than

Cesarean sections or symphysiotomies because there have not been proper opportunities for the general practitioner to prepare for major obstetric operations and he has been justified in his conservation of maternal life at the expense of the infant.

**6. Shock.**—The explanation of shock given by Boise is that there is a tetanoid condition of the heart and peripheral arteries, both together producing a low arterial pressure, from lessened blood supply, and he believes that the cause of the whole is due to over-irritation of the entire sympathetic system; it is not a paresis of the secretory nerves, but an over-stimulation. The remedies which he suggests are nitrite of amyl and nitroglycerin, and he considers strychnin—at present the most popular drug—as positively dangerous. The use of normal salt solution of rather high temperature, 115 to 118, given intravenously is also recommended in preventing shock, though if it is simply intended to supply the blood loss by hemorrhage the subcutaneous method will suffice.

**9. Traumatism of Pregnancy.**—Lewis' article is a lengthy review and discussion of a large number of cases. He favors abdominal section as an easy course and one that relieves the patient more often than does trusting to chance. If no sufficient lesion is found it can not be said that it adds materially to the risk.

**10. Uterine Hemorrhage.**—Several cases are reported by Grandin of persistent hemorrhage from the uterus and of hemorrhage following abdominal section. He believes that, after an elective abdominal section, the word shock means hemorrhage. If internal hemorrhage occurs within twenty-four hours after such operation, as in his patient, it is sufficient to warrant us in re-opening the abdomen. He contends also that vaginal section will enable us to settle this question, which is of vital moment to the patient and to our reputation. We should free our minds, however, of the thought of that bugbear, shock, remembering that the symptomatology is essentially different and that the free use of morphin ought to make a differential diagnosis for us.

**11. Measles.**—The hygienic, dietetic and medicinal treatment of measles is described by Fischer. The first consists in guarding the child from any unnecessary exposure to heat or cold, with thorough disinfection of discharges from the nose, ears and mouth, and securing rest and quiet. If there is an exanthema, mild diaphoretic treatment may be indicated. He advises the use of liq. ammon. acetat in half dram or dram doses every one or two hours to produce diaphoresis. If the temperature is below 102 no further drug treatment may be required. It is important to watch the stomach and bowels, hence stimulation of the emunctories will be urgently demanded in this pre-eruptive condition. All the body functions must be carefully watched. For the medicinal treatment he suggests one-drop doses of tincture of aconite when it is necessary to have both the antipyretic and diaphoretic effect. In very weak or rickety children great care should be used, and where convulsions are likely to occur hot mustard foot baths and the ice bag or cold applications to the head used and bromid of sodium in 10-gr. dose given by the mouth if the nervous symptoms are severe. For vomiting he would give the stomach rest, resorting to rectal alimentation and medication if necessary. Great care should be taken in the use of purgatives. Phosphate of sodium in 10 to 30 gr. in water is a useful laxative and so are small doses of citrate of magnesia. Very small doses of calomel, 1/10 gr., two or three times a day may also be used. We should remember that intestinal catarrh is one of the dangers of the disease. Water should be given liberally; fruit juice may be added to it. When the nose and the pharynx discharge freely and irritate the child, irrigation with some bland antiseptic, such as 1 per cent. boric acid solution, is useful, but if there is a catarrh involving the nose and throat as well as the bronchial mucous membrane and the accumulated secretion is annoying, an emetic is advised. Most children cough and swallow their expectoration and a dose of castor oil may be useful. For emesis he suggests the compound syrup of squills every half hour or syrup of ipecac in dram doses, but when neither of these are effective he finds sulphate of copper in one-half or

one grain doses in the same intervals valuable. For the distressing cough, especially at night, steam, impregnated with eucalyptus or oil of thyme and small doses of codein can be employed. Two or three grain doses of chloral hydrate can be used for a child three years old. He has had little good from heroin and sometimes unfavorable symptoms. The complication of pneumonia requires symptomatic treatment. High fever may require tepid sponging or local tepid pack, but cold baths and cold packs do not seem so well borne as in other febrile diseases. The oiled-silk jacket, if the case is not an abnormal febrile type, covering the whole thorax and applied next the skin is very valuable. Dry cups applied posteriorly are useful for dyspnea. He has used antipneumococcic serum in one case, but of course no conclusions can be drawn. The child made a perfect recovery. If diphtheria is a complication the usual treatment is required. Antitoxin should be considered as early as the diagnosis is made. He does not believe, however, in immunizing doses of antitoxin during the course of measles to protect from possible diphtheria. If the child is nursing, breast milk is the diet to be used. In case of bottle-fed babies the greatest care must be exercised in feeding. With gastric symptoms the interval should be increased and a smaller quantity administered. When violent gastric symptoms prevail in spite of all precautions, absolute rest of the stomach is necessary and rectal feeding should be used if required. In older children buttermilk may be substituted for milk and concentrated foods such as cream and butter may be given. Thus a small quantity of cream rather than a large quantity of milk if the stomach will tolerate it will be beneficial. Soups, broths, eggs and paps of oatmeal and milk are indicated. In older children calf's-foot jelly, chicken jelly, raw scraped steak and oysters in addition to broths and milk and cream may be allowed. Fruit and fruit juices may be given ad libitum. The convalescence and restoration to the normal condition depends on the nutrition rather than on drugs.

**13. Appendicitis.**—The question of how to diagnose appendicitis is the subject of Meyer's article. While he believes it always a surgical disease, he asks whether it is possible to prophesy what course may be followed. As regards the refinements of diagnosis he mentions that it is often possible to locate the position of the acutely inflamed appendix within the first days of the disease by going over the right half of the abdomen with the tip of one finger. Although McBurney's point will invariably be found to be painful to the touch, still more intense pain can often be elicited on pressing a spot above or below the omphalospinous line or posteriorly to the caput coli in the lumbar region. In a case of unmistakable acute appendicitis the greatest pressure pain is found not on but somewhat above this line and along the crest of the ileum or, if it is principally marked in the right lumbar region, we shall rarely go wrong in assuming that the appendix is situated posterior to the caput coli. Dr. Meyer has never been disappointed in this sign. If, on the other hand, digital examination by the rectum or vagina demonstrates the greatest tenderness or a painful mass on the right side of the pelvis, we shall, almost without exception, find the appendix in its normal position. He believes that attempts to directly palpate the acutely inflamed appendix throughout its length are usually unsuccessful and he here gives Meltzer's method of examination as follows: Under normal conditions the appendix should rest in the right iliac fossa, that is to say, on the ileopsoas muscle, from which it is separated by the parietal peritoneum, the extraperitoneal or transversalis fascia and the ileopsoas fascia. Active contraction of this muscle will, of course, increase the volume of the belly of the same and therewith raise the appendix thus situated upward toward the anterior abdominal wall. If now the examining fingers are pressed gently but deeply down into the iliac fossa at or near McBurney's point, and the patient is directed to slowly lift his straightened and outwardly rotated lower extremity so as to form nearly a right angle with the trunk; in other words, if we direct him to thus make flexion at the hip, such an appendix will thereby be subjected to increased direct pressure and hence become still more painful than before. It will also in this way sometimes become more or less distinctly palpable. If, on

the other hand, the result of this kind of an examination is negative, I should think we might be justified in concluding that the appendix is not resting on the ileopsoas muscle, but running in a different direction. Elsberg claims also that: by accepting McBurney's point as the base of the organ, its further course might be determined by the spot of greatest *subjective* pain, as repeatedly pointed out by the patient upon being questioned regarding the same. The doctor stated that in this manner he had succeeded in correctly diagnosing the position of the organ in 49 out of 58 cases. Should further experience prove this method too to be reliable in the greater majority of cases, it may frequently prove of value to the surgeon. If the patient persistently locates the principal subjective pain to the left side of the lower abdomen in a case of undoubted acute appendicitis, we may infer that the vermiform is long and hangs down into the small pelvis. Vaginal or rectal palpation will frequently verify such an assumption. But this diagnosis of location and possibly also of the length of the inflamed appendix is of practical importance to the operator only because it tells him where to incise, while for the general practitioner it is of little value. With him it is not a question of direction, but of recognizing the clinical seriousness of the attack. He further asks if we can conscientiously claim to be able to diagnosticate at the present time with regard to the pathologic lesion of the appendix in its acute inflammation during the first two or three days of the disease, as long as the inflammation is still confined, in its principal part at least, to the appendix as such, and as long—he emphasizes this point—as no tumor of any kind is palpable in the region of the appendix. From the basis of his experience covering hundreds of cases during sixteen years he is obliged to answer in the negative, and he doubts whether we will ever be able to do this. He does not, however, wish to have it understood that we should discontinue our efforts to sharpen our diagnostic capabilities in regard to these points. He advises then in the interest of our patients, that we be satisfied with our ability to diagnose the given case: 1, as one of acutest inflammation, which has already transgressed the border lines of the appendix and involves the peritoneal cavity to a greater or lesser extent, in consequence of a macroscopic perforation of the organ, or without the presence of same; or 2, as one of acute inflammation, that is most probably still confined to the appendix as such, although its immediate neighborhood appears more or less involved; or 3, as one of subacute inflammation. Let us allow such diagnosis to furnish the indication for or against prompt operation. Let us continue to tell the general practitioner to go on diagnosing acute appendicitis first of all on these lines. It is often by no means an easy task for the average man, and in some instances for the specialist, to render the differential diagnosis between acute appendicitis and other acute inflammatory lesions within the abdominal cavity. Let us, therefore, not complicate matters still more by expecting the physician to also diagnose the exact anatomic lesion of the organ before deciding whether or not prompt surgical intervention be needful. As a third division of his subject, he asks what we can diagnose in the degree and extent of a complicating peritonitis. He remarks that in the great majority of cases acute appendicitis is accompanied by localized peritonitis. Localized palpable tumor in the region of the appendix means pus formation or the deposition of plastic lymph with tendency to pus formation in the great percentage of cases. While pressure pain over the left lower abdomen speaks for a more intense, often spreading peritonitis, paresis of the large intestine, tympanitis, continued vomiting, general abdominal and rectal tenderness, dullness on percussion of the right iliac fossa and over the whole lower abdomen suggest a spreading or fully developed general peritonitis with or without effusion. An important sign is pain on pressure in the left lumbar region, the part farthest away from the usual seat of disease—if we exclude the subdiaphragmatic space. With chill and the other symptoms mentioned and pain in the left lumbar region, the diagnosis will then be found to be correct. He gives a point as regards the diagnosis of subacute and acute appendicitis during the interval and says: If a patient was suddenly taken sick with pain in the lower abdomen and consecutive localization of the

same in the right groin, but without the simultaneous occurrence of a number of stools, especially of loose diarrheal stools: and more important still, if nausea and vomiting accompanied the trouble, if gas and feces could not be passed for hours or days, if an increased pulse rate, localized pressure pain and, possibly, rise of temperature were noticed, such a disease was most probably—at least in the male—an attack of acute or subacute appendicitis. If a right movable kidney is present and the attack occurred independently from the advent of menstruation, the probability of the disease having been an attack of acute or subacute appendicitis, gains ground also in the female sex. Further direct examination must clear up such a case. If gynecologic examination be negative, if gallstones can be excluded, if urinary analysis does not point to disease of the kidney, and if we are able to palpate a painful cord, corresponding to the location of the appendix, our diagnosis promises to be correct. He has had little faith in the palpation of appendicitis, and admits his inability to do what is claimed by some authorities. He suggests the danger that palpation may cause rupture of the focus into the general peritoneal cavity or the re-awakening of slumbering processes.

**14. Rheumatic Appendicitis.**—Going over the authorities and replies received to questions sent to physicians concerning appendicitis in the distinctly rheumatic individual, Edwards remarks that the testimony is almost unanimously against the existence of a condition styled rheumatic appendicitis. He would therefore summarize by saying that, 1, the present state of our knowledge does not warrant the use of the term rheumatic appendicitis; 2, there seem to be but two conditions in which rheumatism can at all be considered in etiologic relation to appendicitis, and these are when a rheumatic endarteritis of the single appendicular artery exists and the blood supply is greatly diminished thereby. It seems to be conceded that the entrance of fecal matter of itself does not necessarily give rise to appendicitis, but it is probable that the inflammation may have its origin in the micro-organisms conveyed to the interior of the organ by the fecal matter. Even if rheumatism is an infectious disease and the infection is due to staphylococci, whose seat is in the gastro-intestinal tract, it may be probable that the feces in these cases are unusually toxic, but this again is far from proved, so that when considering a so-called rheumatic appendicitis we must resort to the old Scotch verdict—"not proven."

**15. Mastoid Operations.**—The main points discussed in regard to mastoid operations are summarized in the paper by Hammond as follows: 1. Mastoiditis is always subsequent to purulent inflammation of the middle-ear. 2. Tenderness of the bone is an important symptom when present, but the mastoid may be full of pus, with absolutely no tenderness. 3. Bulging of the canal wall is a most important symptom. 4. The absence of temperature is no guide whatever. 5. Improvement in the hearing is usually indicative of subsiding inflammation in the middle-ear. 6. The operation is safe, and delay may be dangerous.

**19. Palmar and Plantar Syphilids.**—Bernart finds that in 200 successive cases, eliminating patients who had forgotten their history, 17.5 per cent. suffered from either palmar or plantar syphilids or both sometime during their disease. He gives details of some of the cases. He thinks that while this percentage may be larger than that found elsewhere it indicates that such lesions are found more frequently than ordinary observation would lead us to believe. In cases where it occurred, in nearly 60 per cent. both surfaces were diseased; the palms alone followed next with about 25 per cent., while the plantar surfaces were alone affected in only about 1 per cent. Nearly 50 per cent. more of soft and tender hands were affected as compared to others; this shows that irritation and friction do not play an important part in the production of palmar lesions.

**21. The Health of School Girls.**—Brackett finds from statistics that females make up the larger number of applicants for hospital treatment of physical developmental defects. It impresses the physician who sees a large number of children to

observe the large number of girls that are anemic and nervous, and the very marked difference between their condition and that of the boys at the developmental stage. Much of this trouble he lays to the overstrain of our present system of school education and holds that the school is responsible for very many of the conditions in so far as it demands interference with the necessary amount of sleep and outdoor play and it does not sufficiently recognize the difference between boys and girls and between different individuals.

**22. The Health of School Girls.**—Lovett's article follows the same general line, reviewing the facts so far as known and giving such data from his own investigations as he has been able to obtain. He finds that the number of pupils that leave school on account of their health, especially in the high and normal schools, is much greater among females than males. There is no consensus of opinion that girls leave school with their health improved over that at the time of their entrance and some teachers were definite in their statement that the girls were not as well on the average. He thinks the remedy lies in the development of physical training in a proper school gymnasium under proper conditions. For this purpose a gymnasium is imperative as exercises in the school room are not effective. This seems to be the general consensus of opinion among teachers. At present the general health of the school girl at puberty is far from what should be desired and what seems to be the result of school work plus outside demands.

**23. The Health of School Girls.**—Hartwell's article is more confined to statistics than the others and he does not find from his figures that a disproportionate number of girls are obliged to leave the Boston public schools because of impaired health. It is only in the high and Latin schools that the losses are considerable, and if overpressure exists there is where we should expect to find evidence of it. He holds the medical profession fully responsible as educational authorities for the present neglect of school hygiene and the undeveloped state of vital statistics relating to the school population, but he admits that physicians are somewhat more alive than the teachers to the needs of the situation.

**24. The Health of the College Girl.**—Sabine, in taking the statistics of 2000 students in finishing schools and colleges, finds that there is a defect and that the college girl does not represent exactly the type that she should in the physical point of view.

**25. Fourth Disease.**—Griffith considers that it would be a calamity if Duke's fourth disease could be proven to exist. From his study of the subject he says there is no reason for and every reason against its existence. He thinks that every infectious disease is liable to variation in its type both in the individual and the epidemic, and that aberrant cases and forms and even aberrant epidemics occur. We can not give separate names to every such form. The history of rubella shows that it is particularly liable to vary. We have yet to see rubella scarlatiniforme, as generally understood, fail to protect from an attack of rubella morbilliforme or vice versa.

**26. Intermittent Claudication.**—The case reported by Levy was an apparently complicated one showing some of the typical symptoms of Charcot's disease and also some of those of erythromelalgia. He thinks we are warranted in calling it one of those mixed cases which show the close relation between these disorders and Raynaud's disease. The appearance of felons is also mentioned as being analogous to such conditions in Morvan's disease.

**27. Ophthalmia Neonatorum.**—According to Wilson the demands of treatment and prophylaxis of this disease are: 1, the antepartum care of the birth canal; 2, the scrupulous cleansing of the lids following expulsion of the head and constantly thereafter in suspicious cases; 3, the noninvasion of the palpebral sac by separation of the lids before the appearance of typical discharge; 4, prompt and absolute isolation upon the appearance of conclusive signs of specific inflammation; 5, thorough and systematic irrigation; 6, astringent application of silver nitrate in cases of prolonged suppuration. In con-

clusion, as an important adjunct to local treatment attention should be given to the general condition of the child in cases of debility and malnutrition. The measures directed toward the care of the infant are comprised in cod-liver oil inunctions, small doses of whisky internally and breast feeding. At the same time the mother should receive some form of tonic treatment.

**30. Pseudoleukemia.**—Sailer's paper, which was commenced in the last issue, is ended in this. He reviews Sternberg's cases and comes to the conclusion that we can not speak dogmatically as to the tubercular origin of this condition. None of the evidence heretofore presented can be regarded as decisive, but the gradual accumulation of positive facts, as Pinkus says, and the absence of entirely satisfactory negative evidence, rather tends to confirm the supposition that the majority of cases of pseudoleukemia, if not all, will ultimately be recognized as tubercular.

**31. Hepatic Abscess.**—Five cases of hepatic abscess of amebic origin are reported by Osler which are of interest as showing the latency of symptoms and the liabilities to error in diagnosis. In one case the abscess was not large and the symptoms were negative, with absence of fever, chills, sweats and leucocytosis until just before the operation. There was, however, a marked diffuse cyanosis that is still unexplained and localized swelling above the right costal border which was found to be associated with adhesions between the liver and costal margin with no signs of abscess pointing in this direction. In another case the symptoms led to a diagnosis of malignant disease, and still another, of empyema. Osler calls attention to the leucocytosis which was particularly absent in three of the cases. They contradict the statement, made by some, of the invariable presence of this condition in hepatic abscess. In one case there was no ulceration of the intestine, though there may have been dysentery months before which had healed.

**33. Pleurisy.**—Crook describes first a hypothetic case with symptoms diagnosed as pneumonia, but the patient does not pass through the ordinary course of the disease and fails to get well. It is possible the physician may now recognize the true nature and give the diagnosis as pleuropneumonia and save his reputation, but it is not always the case, and sometimes because the condition is not early enough recognized the patient is lost. He emphasizes certain distinguishing points and says the initial chill and subsequent temperature range are not reliable guides; we should hesitate in diagnosing pneumonia without rusty sputum. The variation in the respiration and pulse ratio is important. If the respiration is so increased that the ratio is 3 to 1, 2 to 1 or perhaps 1 to 1, the case is probably pneumonia. A marked increase of the circumference of the affected side may be taken as absolute evidence of accumulation of fluid, but the contrary does not always hold good, for it may force its way upward instead of sideways. Displacement of the viscera, especially the heart, is of the utmost value in effusion, and it should be borne in mind that the border of the percussion dullness does not always show an exact hydrostatic level. In some cases it may even rise to the summit of the lung. It requires a good deal of care to look after these patients. If we are still in doubt we should not hesitate to employ the exploring needle. It is only by this means that we are able to determine positively whether an effusion be of a serous or of a suppurative character, or to diagnose with certainty the presence of encysted accumulations.

**35. Varicose Veins.**—An etiologic classification of varicose veins is made by Terriberry with a distinction between those cases which occur with a predisposing cause and those in which there is no acquired or congenital defect in the vascular apparatus. Further, with or without predisposing cause, all cases of varicose veins may be placed in three groups: 1, those due to regurgitation following stenosis above the saphenous valves; 2, those cases due to regurgitation with stenosis inferior to the saphenous valves, and 3, those cases due to stenosis without regurgitation.

37.—This article has appeared elsewhere. See abstract in *THE JOURNAL* of March 15, §102, p. 734.

**46. Prostatic Hypertrophy.**—The history of operations is reviewed by Ballin, whose conclusions are as follows: 1. The regular use of the catheter in hypertrophy of the prostate gland is dangerous, as it causes inflammatory processes in bladder and kidneys. 2. Therefore prostatic hypertrophy with retention of urine, which would necessitate the use of the catheter several times a day and placing the catheter in the hands of the patient, ought to be treated by operation. 3. Bottini's operation is preferable and sufficient in most cases; some cases are better treated by prostatectomy. 4. A good diagnosis of the kind and shape of prostatic enlargement and of all complicating factors—cystitis, nephritis, etc.—is essential for the selection of the suitable operation, and also for its successful performance.

**56. Enteroptosis.**—Hemmeter finds the etiology of enteroptosis one of the difficult questions. He is rather in favor, however, of the theory of Rosengart that it is a pathologic reversion of the location of the abdominal organs to an embryonic state, at least in congenital cases. He insists that the best means of diagnosing are the finger, the sight and the hearing. He deprecates too much dependence nowadays on technical and artificial methods to the exclusion of the more natural ones which are often more effective in many cases. He mentions especially the change of sound in the stomach containing liquid, the splashing sound and Stiller's sign of the floating tenth rib, which he has found present in 78 out of 130 cases. The introduction of the rectal Langdon tube or sound is of value, and he believes that it can be introduced clear up to the cecal opening. Still another method is distension of the colon by air or water; air alone blown in by bellows will frequently give the desired information without the necessity of the more troublesome method of using water. The treatment of enteroptosis should be directed to strengthen the general constitution by proper diet, hygiene, use of air, electricity, arsenic, massage and baths, all of which have their share of usefulness. The correctly applied plaster bandage laid on the nude figure in strips and a special straight-front corset, which has a tendency to press the intestines upward, thereby making a cushion for the stomach, colon and kidneys to rest on is also very useful. If the patient is emaciated, a fattening cure should be undertaken. Surgical interference is to be avoided.

**57. Enteroptosis and Displacements of the Colon.**—Turck's article deals especially with displacements of the colon, which he considers largely due to the following general etiologic factors: 1. Any condition that induces an increased capacity in the abdominal cavity. 2. Constriction of the thorax. In many cases there are no symptoms, and in some cases of coloptosis the symptoms disappear after treatment, but ptosis remains. There are, however, permanent mechanical disturbances due to prolapse, viz., dragging on the mesentery, pressure on the kidney and weakness of the visceral muscles, producing chronic irritation of nervous symptoms and hysteria and neurasthenia. As regards treatment something might be done for the prophylaxis provided we control the heredity. We are not yet, however, able to do this. For the girl, the advantages of open-air life should be enjoyed and constriction of the thorax should be avoided. As regards the enteroptosis occurring after childbirth he believes that if proper hygienic habits had existed before, artificial support would hardly be required. The principal indications for treatment of colonic displacement are, 1, atony and dilatation; 2, vasomotor disturbance of the splanchnic vessels; 3, lax conditions of the abdominal walls. The methods are similar to those for gastro-enteroptosis combined with fresh air, exercise and dress reform, gastric lavage, abdominal support, rest, abdominal exercises, drugs, nux vomica and laxatives, rectal enemata and abdominal douches. In his own treatment Turck obtains just the same results as in washing out the stomach contents, by the use of a thin rubber bag attached to the end of the tube. This produces a much more effective gymnastic exercise of the pyloric end, and a still more effective method is to use hot or cold air

instead of water. The use of the gyromele produces, as Ewald states, a thorough cleansing of the membrane and its adherent mucus, and, naturally, also a strong stimulation of the gastric wall. Lavage of the stomach in the morning is also useful as Fleiner remarks. Large rectal enemata are harmful as they stretch the intestine and increase atony. Small quantities of water are better. Gymnastic exercises of the colon correspond with those used in the stomach, details of which can be found in other papers by the writer. The treatment of lax abdominal walls by exercise (*International Clinics*, Volume II, 11th series) has proven very satisfactory and where there is a separation of the rectus muscles, which is considered the cause by Webster, the operation he recommends is the best for the condition, with continued prolonged after-treatment.

**70. Lymphatic Leukemia.**—This condition is described by Herriek, who holds that it is probably not so rare as generally supposed, and that the more carefully the blood is examined the more frequently will some of the cases of supposed pseudo-leukemia be found to be genuine lymphatic leukemia. It is a well-known fact that in many pseudo-leukemias a slight relative increase in lymphocytes is met and at times a sudden transformation of the blood, the blood being flooded with lymphocytes. This is the so-called transformation of the pseudo-leukemia into the true lymphatic leukemia. Some authors, including Pinkus, take the ground that there is practically no sharp dividing line between the two conditions and that many transitional forms are met. Herriek also suggests that probably some of the severe anemias, in some cases classed as scurvy and purpura, may show similar blood conditions; the impression is also conveyed that these cases of acute leukemia are acute infections or virulent toxemias. He remarks on some of the peculiarities in the cases that he has seen.

**73. Suggestive Therapeutics.**—Prince's paper is an interesting one, giving an account of a number of cases where he used suggestion with decided advantage, especially in morbid conditions of the eye. He lays especial importance on the operator finding out the key to the patient's delusions, without which it may be impossible to effect a cure even if the entire confidence of the patient is gained.

**85. Sterility.**—This article by four authors reviews the microscopic characters and the morphology of spermatozoa and gives experimental studies and clinical observations of their vitality. The conclusions, which they consider to be fully determined by their study of the subject, are: "In sterile marriages the fault certainly lies with the husband in from 10 to 15 per cent. of cases; probably in a still larger percentage. Though absence of motile spermatozoa is a proof of sterility, their presence does not necessarily demonstrate that the semen is fertile. Microscopic study shows that spermatozoa, although they are alike in general characteristics, differ greatly, even in the same individual, in conformation, size and color reaction. In spite of these differences, it seems possible to recognize the normal and probably fertile organisms. In their passage through the epididymis the spermatozoa undergo developmental changes so marked as to be easily recognizable; hence, it is probable that the epididymis is not a mere conduit. The prolongation of motility is a better index of fertility than the mere fact of motility. The commonest local cause of sterility in the male is obliterating bilateral epididymitis of urethral origin. Bilateral epididymitis is comparatively rare. Permanent obliteration of the tube of the epididymis is its exceptional rather than its usual termination, and is most effectually avoided by prolonged treatment. When the obliteration persists it is in the tail of the epididymis. Azoospermia resulting from obliteration in the tail of the epididymis can be easily and safely overcome by forming an anastomosis between the head or body of the epididymis and the vas. Ejaculations following this anastomosis swarm with motile spermatozoa. Whether these be fertile and whether the vaso-epididymal anastomosis will persist, can be determined only by prolonged observation." An extensive bibliography is appended to the paper.

**95. Strabismus in Children.**—Parker points out the im-

portance of early treatment of strabismus and, in young children who can not yet use glasses, he advises removal of all books, pictures and toys that require close observation, substituting for them, wagons, hobbyhorses, balloons, etc., which do not tax the vision. The child should not be sent to kindergarten, and if these measures do not prevent the squint from developing, a weak solution of atropin, one grain to the ounce, should be instilled into the eyes once or twice daily to partially suspend the power of accommodation. In this way the child may be cared for until old enough to wear glasses, which can be used by some children as early as three years. The shadow test and other means make the fitting of glasses to children perfectly reliable after the complete suspension of accommodation by mydriatics, and a full correction of the refractive errors should be given to be worn constantly. The eyes should be retested once a year and refitted if necessary to decrease the strength of the glass as given to correct farsightedness. The use of glasses will frequently cure the squint, but should they fail, cover the good eye for an hour, twice daily, thus enforcing the use of the squinting eye. By this means the vision may be improved and the loss of co-ordination corrected. The stereoscope can often be used for older children; by marking corresponding points on the two pictures, and asking the patient to interpret them, one can tell which eye or if both eyes are being used. By the variation of pictures the child is not only being treated but entertained. The vast majority of cases, however, will not be cured by means other than surgical, and if at the sixth or seventh years the squint is permanent and constant with or without glasses, surgery should be resorted to. If each test, however, shows a different error, indicating that the abnormal condition is not fixed, it is advisable to wait until the eyes and muscles are more fully developed. A premature operation may lead to a turning out of the eye, while neglect may lead to impaired vision. Success requires the study of each individual case.

**96. Pseudo-Tubercle Bacillus.**—Cowie mentions certain forms of bacilli closely resembling the tubercle bacillus, such as Hanson's bacillus and the smegma bacillus. The only reliable test is animal experimentation for the smegma bacillus, but the catheter test comes next in value. It is made by thoroughly sterilizing the parts, using a sterile catheter and collecting the urine in a sterile receptacle. After this the sediment is examined by staining with hot carbol fuchsin, washing, immersing in 15 to 25 per cent. nitric acid solution and then immediately transferred without washing to absolute alcohol, where the specimen remains a short time until excessive redness is gone. The alcohol is washed off and the specimen counterstained in methylene blue, mounted in water and examined. Any acid-resisting bacilli present are probably tubercle bacilli.

**97. Incipient Tuberculosis.**—Hagadorn lays much stress on the temperature curve in incipient tuberculosis as a diagnostic sign. He regards a temperature that is normal or practically so after 5 or 6 p. m. of great diagnostic importance. The temperature is usually normal between 7 p. m. and 10 or 11 a. m., but as a rule there is a rise between 2 and 5 p. m. of from one to two degrees. The pulse acceleration is also of importance and also gastric disturbance. The physical signs should also be looked for, such as a slightly lessened movement in the supraclavicular or infraclavicular region, diminished expansion of one side of the chest, breathing slightly diminished in intensity, especially during inspiration. The following method he considers very important: The patient's hand is placed on the opposite shoulder. The physician then listens over the portion thus uncovered by the scapula, just above and external to the giving off of the bronchial tubes, where there will be heard prolonged tubular breathing and fine râles on coughing, which is one of the principal signs of phthisis, making diagnosis possible weeks before other signs are present. Contrary to many authors he believes that rheumatic diathesis, when the white fibrous tissue is involved, predisposes to tuberculosis. The hygienic and medicinal treatment are reviewed.

**108. Veratrum.**—Woodward believes in the value of veratrum, especially in inflammatory conditions, and insists on the

importance of a tincture of fresh roots. In a given case of decided phlogistic tendency we should commence with not more than four drops of Norwood's tincture. If at the end of an hour the heart's action is not reduced in frequency or otherwise, give 5 drops and so on increasing one drop an hour until the pulse shows a change. He has such belief in the drug that he says he feels it almost his duty to take off his hat to it "in profound respect for its value."

**113. Enuresis.**—Dupaquier advocates general treatment in the main, directing attention first to the examination of the urine, to the detection of some disease of the blood, from bacterial, metabolic or diathetic source, and depends on the use of water, hygiene, diet and exercise to ameliorate the system first and then the use of local treatment in persistent cases. While belladonna is almost universally recommended, it has to be given in such large doses that it sometimes produces unpleasant and alarming effects.

**114. When Not to Operate in Strabismus.**—Any cause of muscle imbalance, says Robin, whether a tendency to incorrect turning of the eye, aphoria, or an actual malposition, atropia, requires before operation, 1, a thorough study of the patient's age (actual, not in years), employment, general health, social position, character and psychologic state, both habitual and at the time he applies for relief; 2, careful measurement under atropin of all errors of refraction and the constant and persistent wearing of glasses correcting as nearly as possible the total amount of defect; 3, the patient and persevering endeavor in esophoria or esotropia to re-establish balance by enforced rest of the accommodation with atropin and in exophoria or exotropia by muscle gymnastics, general tonics, outdoor exercise and a suspending of all eye work at the near point.

**121. Mercuriol.**—Ayres replies to Lydston's criticism in a former issue of the *Texas Medical Journal*, holding that mercuriol, while not a drug that will control every case, is the most reliable and easily borne preparation of mercury that he has ever used. It can not, however, be given in solution for it oxidizes quickly, a point which has not been mentioned elsewhere than in his former article. He gives it in the form of tablets in 1 gr. dose, three times a day, adding one more grain per day every fourth day until a slight salivation or looseness of the bowels is apparent. Every grain of mercuriol contains 1/10 of a grain of pure mercury which, of course, is a large dose.

**122. Tuberculosis.**—Wilkinson points out the climatic advantages of western Texas for the consumptive.

**133. Intraspinal Cocainization.**—Fort believes that this method of producing anesthesia is usually without serious post-operative symptoms, is not contra-indicated by any condition, and claims its use is imperative when general anesthesia is contra-indicated.

1. **Death from Chloroform.**—The lack of a satisfactory explanation of deaths in the early stage of chloroform anesthesia has incited the research here reported by Embley, who summarizes the different views that have been given and gives elaborate details of his method of experimentation. The present installment of the article includes only the effects on the heart isolated from the central nervous system. He finds, 1, that “chloroform has an immediate and progressively paralytic effect upon the heart muscle. There is no preliminary period of stimulation. There is no abrupt change in the rate of efficiency of the heart. 2. Heart muscle is very sensitive to the poisonous effect of chloroform—a tension of chloroform in blood corresponding to 0.8 per cent. chloroform vapor in the air inhaled kills the isolated mammalian heart in sixteen minutes. 3. In the administration of chloroform by inhalation to the intact animal, the vapor tension of chloroform in the blood only slowly reaches that of the inspired air.”

2. **Agglutinins in the Blood.**—The following are the conclusions of the paper by Ruffer and Crendiropoulo: “1. The cultures of a microbe freed from that microbe by filtration, dialysis or centrifugalization have a distinct though feeble agglutinating effect on that particular microbe. The age of the culture and the constitution of the medium are important factors in determining the quantity of agglutinins present in such cultures. 2. The red blood corpuscles of non-immunized and immunized animals contain no trace of agglutinins. 3. On the other hand, the polynuclear leucocytes of non-immunized animals always possess an agglutinating power greater than, or more rarely equal to that of the serum. They may therefore be rightly considered as the producers, or at any rate the carriers of the agglutinins. 4. In immunized animals the specific agglutinins appear in the polynuclear leucocytes and are therefore probably formed in them. The quantity of agglutinins begin to increase 30 to 48 hours after the injection and goes on increasing up to the tenth day or thereabouts. They then pass into the serum, the agglutinating power of which increases correspondingly. 5. The formation of specific agglutinins in polynuclear leucocytes and in the serum is preceded and accompanied during the first three or four days after the inoculation of a given microbe by an increase of agglutinins for other microbes. This latter increase is of short duration and stops suddenly, whereas the increase of specific agglutinins persists for a much longer time.”

3. **Biologic Test for the Blood.**—Nuttall makes a progress report of the reaction of serum of the blood in different species

of animals. He has tested some 46 bloods of apes and monkeys by means of the “anthuman” serum, the results being in accord with those previously published, that is, the bloods of the *simiidae* give a precipitum apparently equal in quantity to that of human blood, the bloods of *cercopitheidae* give less precipitum, while the least precipitum is given by the bloods of *haplidae* and *cebidae*. The “anthorse” serum has been tested with negative results in 409 bloods, only the bloods of the horse and donkey reacting. “Antidog” serum has given precipitum with bloods of eight species of *canidae*, but not with other bloods. The “antiox” and “antisheep” serums continue to give reactions the same as those of the other reports, that is, they act upon the bloods of other true ruminants and to a greater degree upon the bloods of more closely allied species. One of two “antipig” serums proved to be specially powerful, producing a marked clouding in a number of other mammals' bloods, including man, special species of monkeys, bear, dogs, raccoon, cat, coati, genet, stoat, rat, mouse, antelope and deer. A faint clouding was also noticed in bats and certain species of edentates and marsupials. This seems apparently to contradict the relatively specific character of these antisera, but Nuttall remarks that this is not the case. He finds that a powerful antiserum for any mammalian blood will produce a varying amount of clouding in all mammalian bloods. This he calls the mammalian reaction. These slight reactions would never be mistaken for a full reaction, such as a homologous blood gives. “Antifowl” and “antiostrich” serums are found to act to a greater or less degree on all bird bloods, but not on other forms of bloods, and somewhat similar results are obtained with reptile serum. He describes in detail the method of measuring the degree of reaction, for which the reader will have to be referred to the original and illustrations. He is inclined to believe that with care we shall be able to measure species with this method and find out determinable degrees of blood-relationship which can be formulated.

4. **Leucocytosis and Blood Changes.**—The conclusions of Rogers' article are summed up as follows: “The percentage of the different forms of leucocytosis counted in a stained blood film is of great diagnostic value in differentiating typhoid and malarial remittent fevers, and is easily ascertained. 2. An increase of the lymphocytes to 40 per cent. or over, without any increase in the large mononuclears to about 12 per cent. and upwards, especially during the remissions of the temperature, strongly indicates malaria as against typhoid fever. This change is of great value when parasites are absent from the blood. 4. The presence of myelocytes in any number, such as from 1 to 5 per cent., points to malaria as against typhoid fever. 5. A high degree of anemia, such as a reduction of the red corpuscles to below 3,000,000 per c. mm., is much more frequently met in malarial than in typhoid fever. 6. A very great reduction in the total leucocyte count, such as to below 2000 per c. mm., is much more frequently met with in malarial than in typhoid fever, while the proportion of white or red corpuscles in malaria is not frequently less than 1 to 2000, which is rare in typhoid fever. 7. Leucocytosis can be detected by the presence of a great excess of white corpuscles, upwards of 80 per cent. of which are polynuclears, in a stained blood film, and is often of service in excluding malaria in intermittent fever due to liver abscess or other local inflammation.”

5. **Filariasis.**—Gulland has investigated the blood in one case of filariasis and finds a marked leucocytosis and eosinophilia, which he thinks is bringing filariasis into line with other parasitic affections, such as trichiniasis, which have been known to be accompanied with an extreme degree of eosinophilia. It has been found by Cabot and Brown that extreme filariasis may be present in trichiniasis, etc., which he says seems to show that eosinophilia is concerned in protecting the body from parasitic toxins, whether these are absorbed from the intestines or are actually elaborated in the blood. That the other varieties of leucocytosis have also to do with this would seem to be indicated by the general leucocytosis occurring in his case with the increase of filariasis, but observations are wanting in regard to other parasites.

**7. Pulmonary Phthisis.**—The second Lumleian lecture by Roberts sums up the morbid conditions in the air passages, lungs, pleura, pleural cavity, mediastinal structures, thoracic walls and diaphragm. He sums up the chief practical effects of the various lesions met as follows: "1. There is temporary interference with the action and functions of the respiratory organs, by consolidation and associated changes, or by pleural effusion, which afterwards clears up. These may occur at an early period or during the course of a case and for the time being are often serious. The heart may also be more or less disturbed in its action by such conditions. 2. There is absolute destruction and consequent uselessness, either of a limited area or of extensive tracts, of the pulmonary tissues, thus permanently impairing in various degrees the respiratory function. Even when the phthisical process is arrested after cavities have formed, and the fibrosis has taken place, the involved portion of the lung can be of no further service, though other parts of the organ may take on compensatory work. 3. Morbid products of different kinds are formed, often purulent and of a wasting or exhausting nature and usually discharged as expectoration. Any kind of pleural effusion which has to be removed again and again, as well as empyema, also deserves mention under this head. 4. There is formation and absorption of toxins or other deleterious products—associated with tubercle bacilli, tubercle and its changes, pneumonia, suppuration, etc. It is to these agents that the pronounced general and remote effects of thoracic phthisis appear to be mainly due; no doubt this is a most important pathologic aspect of the disease. 5. Physical embarrassments of different kinds occur, the morbid conditions producing them not being in themselves of an active or serious nature, but being often of much consequence from this point of view, as exemplified by fibrotic changes, extensive pleural adhesions, pericardial adhesions, rigidity of the chest-wall and great muscular wasting. These conditions often materially interfere with breathing power as well as with the acts of coughing and expectoration. They may also embarrass the heart, obstruct the venous circulation, or interfere with particular veins, tubes or nerves. 6. There occur accidental lesions, usually grave in themselves, especially hemorrhage and pneumothorax, for which certain phthisical lesions afford highly favorable conditions. In not a few instances the pathologic effects just indicated are more or less combined in the same case of thoracic phthisis. *Remote morbid conditions.*—In these lectures I am only immediately concerned with the pathologic changes and conditions which are associated with the chest in cases of thoracic phthisis. It must never be forgotten, however, that in this disease other structures are often—indeed, it may be said usually—affected and contribute more or less to its clinical manifestations. Without entering into any discussion it must suffice to state that these remote lesions are either of a tuberculous nature, are well-known secondary non-tuberculous results of phthisis, or belong to the category of accidental or independent complications or complaints."

**8. Typhoid Fever.**—The second of the Milroy lectures reviews the etiology of typhoid, giving numerous illustrative cases showing the effects of water-borne infections.

**9. Vaccination.**—The summary of vaccination results given by Sinigar emphasizes, he thinks, the innocuousness of aseptic vaccination and shows that vaccination is a better protection against smallpox than smallpox is against vaccination. While a staphylococcus was found in the lymph used he points out that in spite of this the majority of arms showed only normal reactions of vaccinia. It is unsatisfactory to note that there are worthless lymphs on the market as it is a source of grave danger to public health and to the reputation of vaccination.

**11. Scarlet Fever.**—Millard argues against the infectivity of desquamation in scarlet fever. He sent out a number of letters to hospital authorities and practitioners and has received a large proportion of answers. The great majority of these admit that they can give little evidence that desquamating epithelium is, per se, a source of infection and that the patient may continue to desquamate for some time after he has ceased to be infectious. Of those who still believe in the infectivity

of scarlatina one or two are a little dubious on the point and can almost be counted on the other side. He sums up the arguments against the supposition that desquamation is infectious, as follows: "1. The absence of evidence supporting it. It is difficult to believe but that, if the old supposition were correct, strong evidence of it would ere this have been forthcoming, as is now the case with discharges from the nose and ears. 2. The fact that infectivity begins prior to the onset of desquamation and frequently continues long after desquamation has ceased. 3. The fact that scarlet fever wards, although abounding in desquamating epithelium, are not a danger to neighboring houses. 4. The fact that the proportion of "return cases" does not appear to be increased among patients sent out from hospital still desquamating. On the other hand, the principal argument in favor of the view that desquamation is infectious is the fact that patients still desquamating, but otherwise apparently free from infection, have frequently been known to convey the disease to others. The whole force of this argument disappears, however, when we consider that patients apparently quite free from infection and in whom desquamation has entirely ceased have also been known to convey the disease; moreover, patients still desquamating have frequently mixed freely with others without untoward results."

**12. Mucin.**—Stuart-Low has utilized mucin as a bactericidal and emollient application in certain cases of aural and nasal disorders, starting with the idea apparently of replacing by something similar to the suppressed natural secretion the arid conditions that often exist in these cases. He has had distinctly encouraging results.

**13. Malaria.**—Birdwood suggests a number of sanitary provisions to be employed in malarial settlements: Among them are a crusade against the obvious anopheles breeding pools and better drainage, providing, for example, smaller drains with cement or stone to prevent stagnant points where anopheles can breed, and using similar preventives in irrigation ditches. There are also many non-obvious localities where anopheles breed which should be looked after. Unsanitary crowding of natives in malarial portions of the tropics is important and especially of servants of Europeans, and he would also provide gauze doors and windows for the barracks of European troops and advise fumigation of rooms and houses. Quinizing the community as advocated by Koch is impossible, of course, in crowded districts, but he thinks quinin should be used more freely. Instructions should be given as regards the cause of malaria and every medical man should be able to make blood films and prepare specimens. Of course, the impossibility of quinizing a whole community, the presence of rice fields, the abundance of anopheles pools are serious matters, but they need not be discouraging.

**18. Plague.**—White reports a case of bubonic plague with a rather peculiar course. A sailor on a line steamer became ill 15 days after leaving Capetown with fever, and swelling in the left inguinal region. He attributed his trouble to a strain received in wrestling. He had a continued temperature, the bubo suppurated and the pus burrowed along the flank. Plague was not suspected and the ship was given pratique. The man was sent to the general hospital at Southampton, where his case was suspected, he was sent to the floating plague hospital for safety, and examinations were made and the bacillus pestis found. The case is one that abused all the ethics of the disease. The man was fifteen days out when he became ill. The bubo suppurated for about ten days, and when the man was almost convalescent from plague the bacillus pestis was found in the profuse discharge.

**29. Intervention in Deformed Pelvis.**—Bar disapproves of induction of premature labor when the pelvis is less than 80 mm. in diameter, and rejects it even with a pelvis of 80 to 85 mm. But he regards it as a good operation with a diameter of 86 to 90 mm., and excellent both in the immediate and the remote results when the pelvis is over 90 mm. The fetus is usually well developed when the diameter is more than 85 mm. and the infants soon compare favorably with the normal standard. Cesarean section and symphysiotomy are still very seri-

ous operations and premature delivery is much to be preferred in case of a pelvis of this size. The mortality of the children is no greater than in deliveries at term. Cesarean section offers prospect of success only when done at the commencement of labor, when the patient is neither prostrated nor infected. Disregard of these indispensable conditions has rendered the statistics more unfavorable than the facts deserve. The same applies also to symphysiotomy, which should never be attempted if there is a chance that the patient is already infected. If she is much prostrated, has temperature and a fetid discharge, both of these operations are contra-indicated and the vitality of the child is already compromised, consequently embryotomy should be preferred. Even in cases in which the mother does not seem to be infected, if the fetal heart beat is indistinct and irregular and the discharge is stained with meconium, there is every probability that the child is no longer viable and embryotomy should be preferred to the dangers of section or symphysiotomy. The latter operation is liable to be followed by prolapse of the uterus, urinary disturbances, with or without laceration of the urethra, and even permanent separation of the pubes. Bar has performed the operation on 25 women. All were sound and the children were healthy. There was no mortality, but serious tardy troubles occurred in a number. Bar adds that 6000 women still die every year of puerperal infection in France, by far the largest majority in the country and small towns. The multiplication of lying-in hospitals where the major operations can be undertaken at need will reduce the mortality from this cause and also the number of necessary fetid interventions.

**30. Utilization of the Extra-Embryonal Part of the Ovum.**—Bouchacourt has been studying for years the natural utilization of the extra-embryonal part of the ovum in various animal species. He thinks that placentophagia is a natural instinct, a kind of opotherapy, and traces its history through the ages as observed in animals and in various folk customs. After establishing on himself the absolute harmlessness of the ingestion of placenta derived from the hospitals or from sheep, he administered the extract to 12 patients with deficient secretion of milk. The results indicate that placentophagia favors the establishment of the secretion, but is unable to induce it when the glands are much atrophied. He noticed that the placenta of sheep had a decided laxative effect.

**33. Treatment of Neurasthenia.**—Romme accepts De Fleury's division of neurasthenia into the two classes, with arterial hypertension and with hypotension. The subjects of the first group have an intoxicated nervous system. Their entire organism is loaded with the refuse of interstitial nutrition. The heart is exhausted and has become hypertrophied in the effort to overcome the resistance in the peripheral vessels. The stomach is hyperpeptic. The great indication is to clean out the organism, the blood and the tissues. A milk diet will afford great relief in a few days. The milk should be given at first about seven times a day, mixed with one-third of some alkaline water. Massage, hot douches and static baths will be found useful, possibly supplemented by exercise, steam baths and pilocarpin to stimulate the functions of the skin. If the stomach proves rebellious, 50 to 100 gm. of artificial serum may be injected subcutaneously every day or alternate day. In both these groups the meals should be taken without a beverage of any kind. In the neurasthenia with hypotension the indications are to augment the strength. Four light meals should be taken, and repose should be enforced instead of exercise. The patients sleep better at night after a nap during the day. Among the tonic measures recommended are salt and sulphur baths, cold or hot douches, deep massage, inhalations of oxygen, ozone and compressed air. But the tonic par excellence is the subcutaneous injection of small amounts of a saline solution increasing from 1 or 2 gm. at first to 4 or 10 gm. He prefers the formula: 1 gm. each of sodium sulphate, sodium chlorid and sodium phosphate in 100 gm. of water, with 50 eg. of phenic acid. These injections are particularly beneficial in amyasthenia, genital asthenia with hyposecretion and in cases of a tendency to torpor, fear or melancholy.

**42. Operating in the First Stage of Ether Anesthesia.**—Sudeck's experiences with operations undertaken during the analgesia that occurs after the first few whiffs of ether, have been confirmed by Teweles and by his own further experience. The condition that follows the first few whiffs is a sort of tipsiness like that following the drinking of alcohol. The subjects still retain their consciousness, but are more or less affected and the sensation of pain is entirely abolished. Sudeck states that it is possible to perform all brief operations in this stage. It has none of the dangers nor inconveniences of profound narcosis and is fully as effective. The patients may resist and scream, but they state afterward that they experienced no pain. He announces that this method is indicated for all operations in which absolute quiet and complete relaxation of the muscles are not indispensable. There is no danger of syncope and the patients are ready for dinner with their usual appetite. In case of failure from any cause the operation can be concluded under general narcosis. Kronacher has recently advocated the cutting short of the ether narcosis, arresting it abruptly at the beginning of the phase of agitation, and announces that the anesthesia thus obtained is ample for the majority of operations. He commences to operate at the stage in which Sudeck is completing his operation. Teweles uses ether from flasks holding only 10 c.c. He administers 30 or 40 c.c. at first and then keeps the patient under its influence with an additional 10 c.c. from time to time as needed. Sudeck now operates almost exclusively under the "ether Rausch" and found it perfectly satisfactory in resection of a callus of the median nerve requiring suture of the nerve, in arthrotomy of the shoulder joint for a tuberculous process, extirpation of a lymphoma on the neck, an arthrotomy requiring thirty minutes, tendoplasty, etc. During these long operations the patient sometimes becomes restless, but in the briefer interventions the operation proceeds without disturbance in most cases. The patients who are most excited before the intervention are the most difficult subjects to operate on and the surgeon should aim to tranquillize them beforehand as far as possible.

**43. Round Ulcer of the Duodenum.**—Laspeyres states that the records show that a large proportion of ulcers of the duodenum cause no symptoms until perforation occurs or hemorrhage. Oppenheimer reports 24 of such cases and Perry and Shaw 91 out of 151. When pain occurs, Boas has noticed that it develops several hours after eating and is located mostly in the right hypochondrium, about 2 cm. below the gall-bladder. In other cases the pains commence earlier, sometimes in a half hour after eating. Occasionally the pain is increased by reclining on the right side, and unlike gastric ulcer, it is not relieved by vomiting. Collin has described a paroxysmal dyspnea simulating pericarditis, observed in one case. The reflex complications of ulcer of the duodenum may be neuralgias, palpitations, shortness of breath, etc. Boas mentions that there is no parallelism between the character of the food and the pains. The latter may develop when the stomach is empty and last into the night, or commence after the patient has retired. Several have noticed that the pains which appeared about two hours after breakfast were banished by ingestion of a little wine and temporarily relieved by the same means after dinner. Boas ascribes this effect of the wine to the dilution of the food in the duodenum and thinks that any fluid would answer the same purpose. Milk and the white of egg bind the hydrochloric acid and might thus be even more beneficial than the wine. The pains are irregular, sudden and like colic at times. The painful region is also sensitive to pressure, but the condition and location varies from time to time and may prove misleading. Boas discovered in several cases a circumscribed tenderness to the right of the spine, close to the twelfth thoracic vertebra. Vomiting is a comparatively rare symptom and is not characteristic unless hemorrhagic. Oppenheimer found that it was noted in only 17 out of 100 cases. It usually occurs at the height of the paroxysm of pain and seems to have no connection with the fullness or emptiness of the stomach. Pagenstecher therefore attributes

it to reflex action, a manifestation of spasmodic contraction or possibly of peritoneal irritation as in the so-called gallstone colic. In 18 cases on record laparotomy was performed on account of acute, general peritonitis, but the operator failed to trace the inflammation to its true source in the duodenal ulcer and all the patients died. The published statistics indicate that 25 to 33 per cent. of all operated cases of ulcer in the stomach or duodenum have been saved. The mortality was only 39 per cent. of the cases operated within twelve hours of the perforation. There are only 3 cases on record in which the ulcer was diagnosed and gastro-enterostomy done before perforation occurred. All of these patients were practically cured and have had no troubles since, for more than five years in one case. One of the patients died of tuberculosis later and the ulcer was found well cicatrized. But there is always the liability that the gastric juice will come in contact with the ulcer after the gastro-enterostomy, and it is still a question whether this operation offers better prospects on the whole than internal treatment.

**44. Treatment of Acute Infectious Diseases with Specific Serum from Convalescents.**—Walger has been continuing his researches in this line and states that he will soon have important results to announce. For the present, he describes the mechanism of the action of these specific sera. The exanthem or infiltration of the lung, etc., in acute infectious diseases are merely the efforts of the organism to eliminate the toxins and the toxin-producers. The production of the toxins raises the temperature by the chemical processes involved. Another factor in the elevation of the temperature is the efforts of the organism to accomplish the chemical transformation of the toxins into harmless substances and then eliminate them in the secretions and excretions. The stimulus to this transformation process is supplied by the micro-organisms themselves. As soon as the toxins have undergone this transformation, the further activity of the micro-organisms is checked. No further toxin is elaborated and the disease process comes to an end. This can be artificially accomplished by injecting the already transformed toxins from another organism which has passed through the various phases of the disease reaction and reached the final phase of transformed toxins and consequent arrest of the morbid activity of the disease germs. The specific serum thus injected arrests the activity of the disease germs in the same way as if the serum had been elaborated in the organism into which it has been injected. But it does not confer subsequent immunity like the latter process. The subject is cured of his disease, but is not henceforth immune as if the recovery had been natural. He is liable to contract measles, for example, as if he had never had the disease.

**45. Differentiation of Cystitis and Pyelitis.**—Rosenfeld states that differentiation is possible by the reaction of the urine, the shape of the corpuscles in the urine, and by the proportions between the pus and albumin. The urine is acid in uncomplicated pyelitis. It may even remain acid in acid cystitis as in tuberculosis or urates. The white corpuscles are round when they are derived directly from the blood, but when they come from the renal pelvis they have an irregular, amoeboid outline. The reds are also degenerated when they come from the kidney, while they are well preserved when derived directly from the bladder. In cystitis the amount of albumin is never more than .1 to .15 per cent. The proportion is much larger in case of pyelitis. With an inch of pus in a liter glass the average proportion of albumin in case of cystitis is .1; in pyelitis .3. With .5 cm. of pus, in cystitis, .06; in pyelitis, .2. With only 1 to 2 mm. of pus, in cystitis traces; in pyelitis .1. In the case of a patient recently observed the urine was acid, the whites amoeboid, the reds degenerated and the albumin was in the proportion of .175 per cent.

**46. Curative Effect of Anesthetics.**—Spiess noted that inflammatory processes healed with striking rapidity when the subjects had been submitted to anesthesia for any cause. He therefore has been studying for years the connection between the anesthesia and the curative action which he has never missed in all his tests. He thinks that the effect is due to a

reflex action of the anesthetic on the vasomotor nerves, inducing changes in the circulation of the inflamed parts.

**51. Technic of Examining the Pupil.**—Schirmer deplors the usual lack of uniformity in the examination of the pupil reflexes by the general practitioner, which renders comparison impossible. He has established that the diameter of the pupil is always the same in the maximal adapted eye with light of 100 to 1100 candle power. Tange asserted in his thesis at Amsterdam last year, based on the measurement of 1000 pupils, that the physiologic diameter of the pupil is between 2 and 4 mm., but in the overwhelming majority it is between 2.5 and 3 mm. Schirmer points out the disturbing influence of passing clouds on the light that reaches the eye in examination at a window. He also states that the adaptation of the eye is unable to follow the diminishing light in approaching twilight; hence examination at this time is unreliable, even although the light may still be more than 100 candle power. He announces that we can assume some disturbance in the centrifugal fibers on one side when the pupils are of unequal diameter when both eyes are illuminated, and also when the pupil of one eye, tested alone, reacts more sluggishly to the light than the other pupil, with either direct or indirect stimulation. We can assume a unilateral lesion of the centripetal fibers, 1, when the light reaction of both pupils is extremely feeble in response to stimulus from that side, while stimulus applied to the other eye induces the normal light reflex; 2, in the cases in which the physiologic diameter of the pupil is abnormal, that is, more than 4 or less than 2 mm.; 3, when the pupil is physiologically wider on this side than on the other. This larger size of the pupil is sometimes the only sign of some anomaly in the centripetal fibers, at a time when the modification in the pupil reflex is still too slight to be perceptible. The pupil reflex is always more sluggish in the elderly than in youth. Schirmer examines both pupils first at 1 m. from a light window for inequality. He then covers one eye and has the subject fix on an object in the distance. After allowing two or three minutes for convergence, accommodation and adaptation, he applies the scale without shading the eye with his head. The other eye is then examined in the same way. This examination of one eye at a time reveals disturbances in the centripetal part of the reflex system impossible to determine in any other way. In one case, for instance, he found the pupil on one side 3.25 mm. and on the other 6 mm., while with both eyes open the pupils were always 3.5 mm. The case proved to be one of unilateral papillitic atrophy. The reflex excitability is then tested on each eye separately. The diagram for each subject mentions: 1, the pupil diameter with both eyes open; 2, of each eye separately, and 3, the direct and consensual reaction of each. He considers other details superfluous in general practice.

**53. Means of Combating Meteorism.**—Oppenheim suggests a means of preventing heart failure in cases of ileus or peritonitis, which he deduces from his experimental researches. The intestines and stomach of animals were inflated by blowing air into the rectum. The diaphragm was forced up and the heart action was fatally interfered with in many instances. In some of the animals he evacuated the air by puncture and administered physostigmin. The results confirmed the experience of veterinarians that this drug is a powerful and certain means of inducing peristalsis. The action is uneven and a large dose may entail torsion of the intestine on its axis or even rupture. The unstriped muscles of the bronchi also experience the specific effect of the drug; this may arrest the respiration when the lungs are compressed by the forcing up of the diaphragm. Froehner has recently published the contraindications for physostigmin in veterinary practice. He says in regard to atropin that the effect is more marked in proportion as the brain of the animal is developed. Young animals bear it much better than older ones. Intestinal peristalsis is promoted by small doses of atropin, which evidently paralyze the splanchnic nerves that inhibit the movements of the intestines. Larger doses paralyze the intestines and induce tympanitis and obstruction. Atropin is rapidly eliminated, but physostigmin has a cumulative action. The former coun-

teracts to a certain degree the effect of the latter. Oppenheim urges further study of this subject as he fears that we are entering upon a period in which the time is wasted on such measures until the ileus or peritonitis may pass the point when the patient might have been saved. His experiments indicate that physostigmin should be suspended when the meteorism has lasted a certain length of time. It has no action on muscles stretched to the point of atony. In his experiments, therefore, he did not inject it until the intestines had been punctured and the distension relieved. He suggests that this technic might be tried as a last resource in desperate cases in order to prevent mechanical heart failure from the upward pressure of the diaphragm.

**56. Incising the Kidney in Acute Pyelonephritis with Miliary Abscesses.**—Wilms relates a case in which the patient was restored to perfect health by slitting the kidney in the course of an acute urethritis, cystitis and ascending pyelonephritis. In order to have as little hemorrhage as possible, the kidney was not cut open as recommended by some, but a small incision was made in the middle and the two halves were then separated by the fingers and a blunt instrument. The kidney was thus slit with the minimum use of the knife and the hemorrhage was trifling. An inflamed kidney can be split in this way much more easily than a sound organ. All of the accessible abscesses were evacuated and the pelvis drained, the gauze drains left inside the kidney as well as around it. Temperature was permanently normal after two weeks. The drains were gradually removed in the course of three weeks and the fistula had healed by the end of the eighth week. The success in this case of small disseminated abscesses shows that suppurative infiltration is curable by this measure. The failures reported by some writers are possibly due to the fact that they sutured the kidney immediately afterward. Free drainage seems to be indispensable.

**57. Suprarenal Diabetes.**—In Metzger's experiments injection of suprarenal extract induced hyperglycemia in dogs and rabbits. Whether the action was by the mediation of the pancreas or of the liver, is still undetermined, but indications point to the latter. The injected substance seems to act on the pancreas and inhibit the functioning of the cells of the organ. The largest proportion of sugar was observed in rabbits injected immediately after both kidneys had been ablated.

**59. Intra-Ocular Galvano-Cauterization.**—Roscher announces that this method of treating infected wounds and panophthalmitis deserves more general adoption. It was first proposed and successfully performed by Van Millingen at Constantinople. He reported preservation of the sight and arrest of the process in three cases of incipient panophthalmitis. The edges of the wound were cauterized in narcosis and the wire loop was introduced through the wound in the sclerotic into the vitreous body and was then twisted around, bringing it into contact with the entire length of the wound and all the injured tissues. The current can be turned on before or after it is inserted. The operation was complete in three or four seconds, and the instrument was introduced to a depth of 4 to 8 mm. The conjunctiva was then sutured over the hole in the sclerotic, atropin instilled and the eye dressed. The injury of the sclerotic in each case had been followed by severe infection, intense pain, edema of the lids, chemosis and hypopyon. All recovered after this single intervention, with vision of 3/6, 6/6 and 5/25. Roscher describes another case of injury of the sclerotic from which protruded a plug of purulent vitreous humor. The plug was pulled out and cut off, the cold loop introduced and the vitreous body and edges of the wound thoroughly cauterized. Narcosis was not induced and the conjunctiva was not sutured. The eye healed perfectly in a short time and vision has remained at 5/5 during the six months since. Eversbusch found the operation equally effective in a case of post-operative infection. Three similar cases have been reported by Bäumler and Van Millingen and Roscher adds another. He also describes two hopelessly doomed cases in which he attributes the preservation of a good shaped stump to the arrest of the infection by intra-ocular galvano-cauterization.

**60. Position of Homeopathy in Modern Medicine.**—Petitions have been presented to the authorities in some of the German states asking for the establishment of a chair of homeopathy in the medical colleges. Kunkel defines the present status of homeopathy and affirms that it would be "the worst of crimes, sinning against truth," to lead youth into such paths. He adds that not one of the innumerable achievements and forms of progress in scientific and practical medicine have ever been the work of a homeopath. The general public health in Germany is on a higher level now than at any other period in history, but the homeopaths, have not contributed the slightest share in this progress, based on the study of the causes of disease. He points out that the minute doses of homeopathy never induce any reaction in frogs or rabbits, and that the result of their administration in man must be accepted as the effect of suggestion, never as that of the medication.

**63. Treatment of Rheumatic Heart Affections.**—Bensen calls attention to the remarkable influence of the exhalations from natural sulphur waters on the heart action. The sulphuretted hydrogen gas retards the pulse and proves effective in treatment of heart affections consecutive to rheumatism. He found that the pulse was slower by four to ten beats in healthy persons after they had spent an hour or two in the inhaling rooms over the sulphur springs. He thinks that this course of inhalation treatment deserves a prominent place in the treatment of recent rheumatic heart affections and in cases of arrhythmia and the resulting disturbances. The gas has a certain bactericidal effect, but this can not explain the benefits derived in these cases. He is inclined to attribute it to a paralyzing action on the sympathetic or on the pulse-accelerating mechanism of the heart. He reports twenty cases thus treated and all completely cured in the course of six weeks. In certain cases he supplemented the inhalations by sulphur baths two or three times a week. He ascribes the infection of the heart in many cases to the penetration of disease germs directly from the air passages, and urges the necessity of thorough rinsing of the mouth with disinfectants and gargling in every case of follicular sore throat.

**65. Practical Application of Artificially Induced Hyperemia.**—Bier details the technique of artificially inducing hyperemia, both the active by heated air and the passive congestion by constricting bandages. He urges the use of simple apparatus for the hot-air treatment, such as can be obtained by every practitioner—an ordinary box, coated with soluble glass inside and out, a lamp and flaring elbow pipe entering the box. The passive congestion promotes the formation of bone and connective tissue. It is bactericidal and arrests or attenuates pain in a most remarkable manner. It has also a dissolving action, but there is no re-absorption while it lasts, and consequently it must be followed by massage in deforming joint affections, persisting extravasations, etc. He applies the constriction in such cases for eight to ten hours. This is followed by massage and the limb is then raised for an hour or two. Similar and even more powerful results can be obtained by a modification of Junod's boot—a metal cylinder with rubber airtight curtains at each end. It is put on over the joint and the air is aspirated until the subject experiences pain. The air is then allowed to re-enter and is again aspirated to the limit of endurance, every five minutes for twenty minutes a day. The congestion induced by this means is much more effective than by constriction alone. He has found the dissolving action of the artificially induced hyperemia, both active and passive, remarkably effective in curing morbid deposits and adhesions. Some of his patients of this class have been under treatment for four years. The benefits of the passive congestion are most strikingly apparent in painful tuberculous joint affections. He usually applies it as long as improvement is manifest, then alternates it with immobilization and local injections. The hyperemia induced by constriction must stop short of causing pain. The congested part must be warm, a bluish red and edematous. Cold congestion is injurious. The application should be made intermittently to allow the edema to subside before the hyperemia

is again induced. It has proved exceptionally valuable as a means of treating gonorrheal, pyemic and rheumatic joint affections. It is applied in these cases during the day, removed at night, and the limb elevated. All pus and effusions must be evacuated before the passive congestion is induced, the application and the elevation of the limb then alternating hour by hour. Bier reiterates emphatically that it is certainly the best means at our command for the treatment of gonorrheal joint affections. It has also attenuated and abbreviated the course of recent erysipelas in the 20 cases in which he has applied it. It is of course contra-indicated in all cases in which gangrene is threatened. Skillfully applied, it may abort a phlegmon. An elastic band around the neck induces passive congestion in the head, and he has by this means permanently cured a number of cases of chorea. Congestion can be induced on the trunk by a cupping and aspirating appliance on the same principle as above described. He has had ten years' experience with heated air as a measure to promote re-absorption in elephantiasis, chronic local edema, etc., and the results have been extremely satisfactory. Perhaps its most welcome effect is the relief of neuralgia and of pains in the joints. The heated air has a marked stimulating and gymnastic action on morbid blood vessels, varicose veins, etc. The antibacterial action is probably due to the heat. Deep-seated processes are frequently aggravated; active hyperemia is therefore contra-indicated in tubercular joint affections. After the application the patients are rubbed dry; they then put on dry clothes and rest in a warm room for an hour.

**66. Myogenic Pseudo-Angina Pectoris.**—Rosenbach describes four varieties of myogenic affections: myopathic migraine, a pseudo-pleural myogenic affection, myopathic cardialgia, gastralgia and myogenic asthma, besides the muscular pseudo-angina pectoris. The symptom-complex in the latter suggests true angina pectoris, but it is distinguished by the peculiar sensitiveness of the ensiform cartilage, the sternum and of certain portions of the intercostal, neck and shoulder muscles. Also by the fact that the patients feel most comfortable in the dorsal decubitus. The pulse is never accelerated nor retarded, and when the attack subsides the subjects are completely restored and can run, climb, etc., without disturbance. Massage is effective when the muscles involved are superficial. Diaphoretics are also useful. The induction current with large electrodes often proves effective. But the magic effect of the antirheumatic remedies, one-fourth to a gram of antipyrin or phenacetin, will differentiate the myogenic origin of the pain. Functional myopathy of the muscles of the abdomen or back is one of the most frequent and most often misunderstood causes of paroxysmal abdominal pains. They are usually ascribed to a stomach affection.

**67. Effective Treatment of Septic Endocarditis.**—Wenckebach proclaims that his experimental and clinical research and experiences have demonstrated that Credé's soluble silver has the property of hastening certain reactions in the organism which usually occur slowly and gradually. Under the influence of intravenous injections of a 1 or 2 per cent. solution of the silver they pass through all their phases with lightning rapidity. The bactericidal property of the blood is enormously increased. The silver is rapidly eliminated and hence the injections have to be frequently repeated. He was amazed at its efficacy in the cure of septic endocarditis in a lad of 15 and in a young woman, the only cases of the kind that have come under his observation since he began using the collargol.

**68. Olive Oil in Treatment of Stenosis of Pylorus or Duodenum.**—Cohnheim reports 11 cases of stenosis which he was on the point of referring to the surgeon as all internal treatment had failed, when olive oil was tried as a last resort. About 100 to 150 c.c. of warmed olive oil were taken in the morning before breakfast, after which the patients reclined on the right side for fifteen to twenty-five minutes and ate nothing for an hour. If the pains persisted an additional 50 c.c. were taken on retiring. After the first, one or two tablespoonfuls were taken a half-hour before meals. All the patients took the oil without repugnance and no inconveniences were observed

in any case. No nausea nor diarrhea. They were all relieved from their discomfort and the stagnation and the cramp-like pains were abolished. Some of the patients took 50 c.c. of the oil one hour before eating or it was introduced through a sound. The oil answers three purposes: it arrests the pains, obviates friction and serves also for nourishment. It has no action on purely nervous or hysteric stomach cramps and thus serves to differentiate them. This oil treatment renders surgical intervention unnecessary in many cases, even with pronounced gastrectasia. It is especially effectual in relieving stenosis not due to an organic obstacle. Cases of cicatricial stenosis of the pylorus or duodenum are relieved and have no further discomfort with observance of ordinary precautions. The oil in these cases acts mechanically by diminishing the frictional resistance. Cases of relative stenosis clinically manifested by continuous hypersecretion and spasm of the pylorus a few hours after the principal meals, are also materially improved or completely cured by the oil. It should be given a thorough trial in all cases before operating.

**69. New Principles for Combating Pain.**—Schleich compares the neuroglia and neurolemma to the insulating wrapper of an electric cable. When there is a defect in either, some of the current is lost, and in the case of the nerve, the escaping current and resulting short circuit is experienced as pain. If a point painful on pressure can be discovered along the course of a nerve trunk in a painful affection, the injection of some indifferent fluid, or better still, an anesthetic, will loosen the fibers of the insulator and by the edema it induces close the defect and restore the intact conductivity of the nerve. Jürgens has found that the injection of oil answered the purpose, but Schleich prefers his anesthetic mixture. The same end is attained by Bier's passive congestion and other measures which induce this therapeutic edemization of the insulating sheath. He therefore urgently advocates that when points very painful on pressure can be discovered along the course of a nerve trunk, an anesthetic solution should be injected. Pure neuralgia and the intercostal and trigeminal, also sciatica, occipital headache and peri-articular pains are promising affections for the application of this measure. Injection of any indifferent fluid may prove useful in the same manner in chronic inflamed tissue in which constricting processes include the nerve trunk or pull on it, and in cases of neuroma and peri-articular atrophic conditions. The hydraulic loosening of the fasciculi may release the nerve and cure the pain. In incipient inflammation cold applications are most useful in controlling pain on account of their contracting action on the vessels, thus diminishing the pressure on the tissues. But when the tissue is already loosened by the inflammation, warmth is more effective on account of the hyperemia induced. The relief experienced by rheumatic subjects in a hot bath is due to the hyperemia which augments the inhibiting function of the neuroglia. Local application of heat to the spine has a remarkable effect in the same way in relieving pain even at a distance, by the enhanced inhibiting function. Schleich has found that pain may be relieved when the patient lies on two long narrow bags of hot sand, one on each side of the spine. This induces local hyperemia of the spinal insulator, and consequent exaggerated inhibition. The same effect can be obtained by inhalation of an anesthetic. He reports twelve cases of violent biliary or renal colic relieved instantaneously by inhalation of his anesthetic mixture, not sufficient to induce narcosis, but merely to abolish pain while the consciousness is retained. The patient becomes drowsy as the pains subside and falls asleep for several hours. He has found this initial stage of anesthesia exceptionally effective in relieving severe rheumatic pains. He therefore recommends it unhesitatingly for all very painful affections as less dangerous than morphin and more certain in its effects. His mixture is a combination of 2 parts ethyl chlorid, 4 parts chloroform and 12 parts ether; the whole representing a boiling-point of 38 C. He states that there are now on record 10,000 profound narcoses obtained with it, and only one death has been reported, and in this fatal case his explicit directions in regard to the pupil signs had been disre-

garded by the operator. He ascribes the analgesic effect of the anesthetic to the vasomotor exaggeration of the inhibiting function by the hyperemia of the neuroglia of the posterior horns.

**71. Treatment of Laryngeal Tuberculosis.**—Tovolyi has been making a special study of the new remedies advocated for the treatment of this affection. His experience tends to demonstrate that a combination of several is most effective: phenol sulforicinum during the stage of diffuse infiltration and intense inflammation, orthoform oil to combat the dysphagia and lactic acid as the process is subsiding.

**76. Bilateral Total Paralysis of Recurrent Nerve.**—Mygind adds another to the sixteen cases of this condition published in the literature. In his patient the examination of the larynx revealed a hitherto unsuspected carcinomatous stricture of the esophagus. Cancer of the esophagus or thyroid was noted in eight of the other cases; sarcoma and struma in two others. Pericarditis, aneurysm of the aorta or diphtheria were mentioned in the others. There is only one case known in which the vocal cords regained their function.

**79. Method of Sterilizing Catgut.**—Claudius recommends the method of sterilizing and preserving catgut which has been thoroughly tested and is now currently used in Bloch's surgical service. Ordinary raw catgut is wound loosely on glass spools, two threads on a spool. The spool is then placed in a solution of one part iodine and one part potassium iodide in 100 parts water. The jar is labelled with the date, and in eight days the catgut is ready for use. It is kept in the iodine solution until wanted, when it is transferred to another vessel containing a carbolyzed solution. The length of thread desired is cut off under the surface of the solution and the spool is returned to the iodine solution. This iodized catgut is black, completely sterile, and has a peculiarly appropriate consistency, not mucilaginous nor sticky, but plastic, elastic, and it ties like a fine soft copper wire. He reports tests which demonstrate the perfect sterilization of the catgut and also the harmlessness of the iodine, which has the property of being a powerful antiseptic while it does not irritate the tissues. It seems to have the tendency to form a harmless combination with the organic fluids. Catgut left for five months in the iodine solution was as perfect in every respect as that freshly prepared. If left for twenty-four hours in the carbolyzed solution the iodine dissolves out and the catgut loses its peculiarly fine consistency and becomes like the catgut sterilized by ordinary methods.

**81. Bacteriologic Tests of Disinfectants for the Mouth.**—Pelnar's tests demonstrated that none of the widely advertised mouth washes are more bactericidal than ordinary water to which a little alcohol has been added. Gargling, even for ten minutes, with a 6 per cent. solution of "odol," etc., as directed, is utterly useless from a bacteriologic point of view. The microbes are not destroyed nor even checked in their growth. Even more concentrated solutions applied directly to cultures produced no effect in less than several hours.

**82. Relations Between Obesity and Glycosuria.**—Kalinczuk has observed a number of cases at Marienbad in which obese persons exhibited a glycosuria which disappeared as the weight was reduced to physiologic limits. He is inclined to attribute the glycosuria in these cases to fatty degeneration of the liver, as the restoration of the liver to normal was rapidly followed by the vanishing of the glycosuria. One or more courses of mineral waters reduced the obesity and banished the glycosuria in every case in his extensive experience at Marienbad. The alkaline saline waters answer several indications in these cases and are preferable to mere dieting of the obesity. The normal limits of fat for each individual can be determined by daily examination of the urine and the patients must repeat the course of mineral waters as often as needed to keep within these limits.

**83. Operative Treatment of Rhinophyma.**—Wedge excision and suture is only applicable in exceptional cases of this condition. Subcutaneous excision of the connective tissue is liable to result in necrosis of the flaps, but both of these

methods of treatment have the advantage of rapid healing. Rusch prefers peeling off the outer layers and excrescences, leaving a foundation of skin tissue beneath, which soon heals over to restore the defect. In his cases the healing of the operated portion was accompanied by the disappearance of the acne elsewhere on the face. This may have been due to the relief of the congestion by the loss of blood during the intervention. There has been no recurrence in either case during the one and two years since. Transplantation of flaps is not necessary. The raw surfaces soon heal over.

**87. Antiquity of Bubonic Plague.**—Ebstein asserts that no reliable mention of the bubonic plague has been discovered in the medical lore of ancient India. The first description of it is found in the writings of the medical men of Alexandria, the famous Egyptian medical school, during the first century before Christ.

**88. Phlyctenular Conjunctivitis.**—Hilbert investigated 100 children affected with phlyctenular conjunctivitis and found swollen serofulous glands in 73, serofulous eruptions in 22, and rachitis and serofula in 5. This association with serofula can not be a mere coincidence, and he proclaims that treatment of the conjunctivitis should aim first to cure the serofulous condition. He has found cod liver oil, iodine, baths, etc., the best general measures and supplements them by insufflation of calomel into the eye once a day. The eye is rinsed out several times a day with a tepid solution of boric acid. In case iodine is being taken internally, the calomel can not be used on account of the danger of the formation of sublimate. He therefore substitutes a salve of the yellow oxide of mercury in five parts of vaselin. Caustic remedies are distinctly injurious. Under this combined treatment the affection is cured in six to ten days.

**91. Influence of Central Nervous System on the Organic Transformations.**—In this communication from Lombroso's Institute of Legal Medicine and Psychiatry, Modica states that the removal of the frontal lobes in animals had a marked effect in diminishing the elimination of nitrogen and the total phosphates in the urine, while the earthy phosphates almost entirely disappeared. Further tests—removing or destroying portions of the occipital or parietal lobes—failed to demonstrate any influence of this kind on the organic transformations. He is now engaged in studying the changes in the metabolism after destroying separate portions of the brain by scalding with boiling water forced through a two-way sound. The necrosis that results is accompanied by the minimum of disturbance in the adjacent tissues.

**92. Analysis of Urine in Determining Age of Neonatorum.**—The presence of chlorids in the urine is not indicative of the age nor of the possibility of extra-uterine life. The phosphates, on the other hand, are valuable from this point of view. In 109 analyses of urine from 25 infants it was impossible to detect the phosphates in the urine before two complete days of extra-uterine existence, and the traces were not distinct until the third and fourth days.

**94. Nature of Blood Serum.**—Buffa points out the difference between the behavior of the serum and of the urine, for instance. When ice forms on urine representing merely 12 per cent. of the water contained in it, there is an increase of more than .006 in the density of the urine below. But ice can form on blood serum to a thickness representing 35 per cent. of the total fluid, without altering the density of the fluid below nor of the ice itself. The serum, therefore, does not obey the laws of an ordinary solution. The water and the salts are evidently combined with the proteid molecules.

**95. Phototherapy of Ozena.**—Dionisio reports eight cases all remarkably improved and some radically cured under a course of phototherapy. If the benefit derived proves to be permanent, the results encourage the widespread application of this treatment. He reflected the light into the nose in some cases and in others introduced a small electric lamp with water circulating in its walls, or used a larger electric lamp

placed in the back of the mouth. The transparency of the facial bones and nasal fossæ allowed the penetration of the light. Still another method he found useful was the concentration of a powerful light on a glass tube in the nostril.

**96. Cutaneous Sensibility in Case of Visceral Lesions.**—Tedeschi's research confirms Head's assertions on this subject. He found that the hyperalgesia in appendicitis was most marked in the tenth dorsal zone, while the twelfth dorsal zone was the seat of the maximum of hyperalgesia in case of salpingitis. The painful region extended from a point above the crural arch to about half its length. This difference in the location of the hyperalgesia may serve to differentiate the two affections in dubious cases.

**99. The Nerves of Taste.**—In two cases operated upon by Biondi for neuralgia by the Krauss-Hartley method, Fasola has studied the course of the taste fibers in the tongue; he concludes that the trigeminus has really its own gustatory fibers, which pass to the anterior marginal parts and to the point of the tongue either directly by the lingual branch of this nerve or by passing in the chorda tympani from some more central point, for example, across to the branch of the otic ganglion. Admitting that the chorda contains a part of these gustatory fibers of trigeminus origin does not exclude that they may also contain others coming from elsewhere, for example, by the intermediation of the nerve of Wrisberg and the glosso-pharyngeal. We thus admit in the chorda the existence of fibers of various origin to explain the persistence in the first days after the operation of a certain taste sensibility and the return of complete, or certainly very conspicuous, sensibility at a later period. These conclusions, he remarks, agree in part with the views of Schiff, but not absolutely.

**100. Infantilism from Pellagra.**—From a study of his case Agostini concludes: 1. That intoxication by the poisoning of diseased maize in the parents, especially in the mother during pregnancy, can produce in children a condition of precocious exhaustion of vitality with degenerative characteristics and retardation of organic development. 2. That in these hereditary pellagra cases we find a high percentage of mortality, a predominance of degeneracy characteristics, especially of cranial anomalies, and quite usually arrest and delay of the development of the body to a point of true dystrophic and myxedematous infantilism and the extinction of procreative power. 3. That the thyroid disturbances found in the cases described of hereditary pellagrous arrest of development are frequently met with in pellagra patients, showing the ready morbidity of this gland in the presence of the specific poisoning and explain the dystrophic or myxedematous phenomena and tend to the aggravation of the symptoms of pellagra intoxication.

**102. Study of Alimentary Infection.**—Galeotti tabulates the various cases of established infection from food which have been published, with details of symptoms, etc. It is evident that putrid meat and infected mollusks are capable under certain circumstances of causing infection which develops with ordinary gastro-intestinal symptoms and signs of general intoxication. The micro-organisms causing the infection may be saprophytes acquiring pathogenic power from some modification in their host or from the lack of resistance of the person who ingests them. He then describes a serious epidemic disease traced to a certain kind of fish, ordinarily eaten with impunity. He was able to isolate a toxic bacterium from these fishes and reproduce the symptoms in animals. The tests were renewed a year later under the same conditions except that the epidemic of the year before had not been repeated. He succeeded in isolating again the same bacterium, but at this time it had no pathogenic power and the tests on animals were invariably negative.

**103. Experimental Research on Intestinal Peristalsis.**—Fasola concludes from the extensive research described that true antiperistaltic contractions never occur, either in physiologic or in pathologic conditions.

**110. Treatment of Tuberculosis with Sulphid of Allyl.**—Guerra has used sulphid of allyl—better known as oil of garlic

—in 17 cases of tuberculosis, and is convinced that it possesses marked antitoxic properties while it is a powerful tonic and stimulant. All of his patients were clinically cured. He followed the directions given by Sejournet of Rheims with slight modifications, injecting 1 c.c. of the following solution: 1 gm. each of sulphid of allyl and sulphuric ether; 20 gm. of eucalyptol and 100 gm. of olive oil. The injections were made under the skin of the back or leg, every fourth day, increasing each time by .5 c.c. until the dose of 3 c.c. was reached and then suspending treatment for a week or two. The sulphid of allyl is eliminated by the lungs; to disguise the garlic odor he has the patients rinse the mouth with an aromatic solution before and after eating and on retiring. He announced from his experience that while it is not a specific, yet this treatment is the most rational of all modern methods on account of its influence on the general health, the appetite and digestion.

**111. Treatment of Convulsions.**—Lamicq distinguishes between convulsions due to some affection of the nerve centers and those due to an intoxication of the organism. The latter should be treated by hastening the elimination or neutralizing the toxic substance. The convulsion itself does not require direct treatment unless it assumes a dangerous phase. Ordinarily the convulsion occasions an abundant elimination of the toxin causing the disturbance, and is thus directly beneficial and should not be combated. The hypo-algesia or anesthesia noted before the convulsions disappears afterward in many cases. Paralysis, uncontrollable vomiting or any persisting hysteric trouble is liable to vanish during the course of the convulsive attack and sometimes permanently. Gilles de la Tourette has even suggested the advisability of inducing convulsions by compression of a hysterogenic zone or other measure, as a last resort in treatment of rebellious hysteric manifestations.

**123. Absorption of Iron.**—Poulssoen recommends the standard liquor ferri albuminati of the Norwegian pharmacopeia as the best means of administering iron. It is inexpensive and contains the least alcohol of any of the usual preparations of iron. The latter fact commends it particularly for children.

**124. Nitropropiol or Indigo Test for Sugar in Urine.**—Thesen places a high value on Hoppe Seyler's indigo reaction as a method of determining the presence of sugar in urine. It is based on the fact that indigo is formed from ortho-nitro-phenyl-propiol acid by the reduction of sugar in an alkaline solution. The test is simple, inexpensive and deserves more general adoption. It has been much simplified by the recent improved nitro-propiol tablets which have been put on the market for the purpose.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS, comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume VI. Gynecology, Edited by Emilius C. Dudley, A.M., M.D., Professor of Gynecology, Northwestern University Medical School. With the Collaboration of William Healy, A.B., M.D. March, 1902. Cloth. Pp. 212. Price, \$1.25. Chicago: The Year Book Publishers.

SOME THOUGHTS ON THE PRINCIPLES OF LOCAL TREATMENT IN DISEASES OF THE UPPER AIR PASSAGES, Being Two Lectures at the Medical Graduates' College and Polytechnic, on October 2 and 9, 1901. With an Appendix Consisting of Two Letters Published on November 23, 1901, and on January 11, 1902, in the British Medical Journal. By Sir Felix Semon, M.D., F.R.C.P., Physician Extraordinary to H. M. the King. Cloth. Pp. 130. Price, \$1.00. London: Macmillan & Co., Ltd. 1902.

GENITO-URINARY DISEASES AND SYPHILIS. For Students and Practitioners. By Henry H. Morton, M.D., Clinical Professor of Genito-Urinary Diseases in the Long Island College Hospital. Illustrated with Half-tones and Full-page Color Plates. Pp. xii-372. Price, extra cloth, \$3.00 net. Philadelphia: F. A. Davis Company, Publishers.

TRANSACTIONS OF THE NATIONAL ASSOCIATION FOR THE STUDY OF EPILEPSY AND THE CARE OF EPILEPTICS, at the First Annual Meet-

ing, held in Washington, D. C., May 14 and 15, 1901. Edited by William P. Letchworth, LL.D. Paper. Pp. 221. Price, \$1.00. New York: C. E. Brinkworth. 1901.

THE UNITED STATES ARMY, GENERAL HOSPITAL, PRESIDIO, California, During the Years 1900 and 1901. Reports of its Commanding Officer, Lieut.-Col. Alfred C. Girard, Deputy Surgeon-General, U. S. A., to Brigadier General Geo. M. Sternberg, Surgeon-General, U. S. A. Paper. Pp. 110.

MANUAL OF CHILD-BED NURSING, WITH NOTES ON INFANT FEEDING. By Charles Jewett, A.M., M.D., Sc.D., Professor of Obstetrics and Diseases of Women in Long Island College Hospital. Fifth Edition, Revised and Enlarged. Cloth. Pp. 84. Price, \$0.80. New York: E. B. Treat & Co. 1902.

THE CAUSES OF DEATH AMONG THE ASSURED IN THE SCOTTISH WIDOWS' FUND AND LIFE ASSURANCE SOCIETY. FROM 1874 TO 1894 INCLUSIVE. Reported by Claud Muirhead, M.D., F.R.C.P.E., Medical Officer of the Society. Cloth. Pp. 81. Edinburgh: R. & R. Clark, Ltd. 1902.

ANOMALIES AND DISEASES OF THE EYE. By Flavel B. Tiffany, A.M., M.D., Professor of Ophthalmology and Otolaryngology in the University Medical College of Kansas City, Mo. Cloth. Pp. 619. Price, \$3.00. Kansas City, Mo.: Hudson-Kimberly Publishing Co. 1902.

EXPERIMENTELLE UNTERSUCHUNG UND MENSCHEN ueber den Einfluss der Muskelarbeit auf den Stoffverbrauch und die Bedeutung der einzelnen Nährstoffe als Quelle der Muskelkraft. Von Prof. H. Newton Heinemann, M.D., aus New York. Cloth. Pp. 36. 1901.

MANUAL OF ANTENATAL PATHOLOGY AND HYGIENE. THE FOETUS. By J. W. Ballantyne, M.D., F.R.C.P.E., F.R.S. Edin., Lecturer on Midwifery and Gynecology, Medical College for Women, Edinburgh. Cloth. Pp. 527. Edinburgh: William Green & Sons. 1902.

TRANSACTIONS OF THE KENTUCKY STATE MEDICAL SOCIETY. New Series, Volume IX. Forty-sixth Annual Meeting, Held at Louisville, May 22, 23 and 24, 1901. Cloth. Pp. 272. Louisville: John P. Morton & Co. 1902.

INTRODUCTION TO MATERIA MEDICA AND PRESCRIPTION WRITING. By O. T. Osborne, M.A., M.D., Professor of Materia Medica and Therapeutics at Yale Medical School. Cloth. Pp. 64. New York: Stettiner Bros. 1900.

WHAT A WOMAN OF FORTY-FIVE OUGHT TO KNOW. By Mrs. Emma F. Angell Drake, M.D., Graduate of Boston University Medical College. Cloth. Pp. 211. Price, \$1.00. Philadelphia: The Vir Publishing Co.

REPORT OF MAJOR W. C. GORGAS, Chief Sanitary Officer of the City of Havana, Report of the Chief Surgeon of the Department, Report of the Superintendent, Department of Charities. Paper. Volume IV.

TEXT-BOOK OF ANATOMY AND PHYSIOLOGY FOR NURSES. Compiled by Diana Clifford Kimber, Graduate of Bellevue Training School. Cloth. Pp. 275. Price, \$2.50. New York: The Macmillan Co. 1902.

TRANSACTIONS OF THE IOWA STATE MEDICAL SOCIETY. Volume XIV. Fifteenth Annual Session, 1901. Cloth. Pp. 478. Cedar Rapids, Iowa: Record Printing Company. 1901.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., April 3 to 9, 1902, inclusive:

Julien R. Bernheim, contract dental surgeon, now at San Francisco, Cal., will report for transportation to Manila, P. I., for duty in the Division of the Philippines.

William N. Bispham, lieutenant and asst.-surgeon, U. S. A., leave of absence for one month granted, to take effect on his arrival in the United States.

James B. Ferguson, contract surgeon, former orders so amended as to require him to proceed to Boise Barracks, Idaho, for duty at that post.

Edward T. Gibson, captain and asst.-surgeon, Vols., recently appointed and now at San Francisco, Cal., to report for temporary duty in the Department of California, and for assignment on a transport when a vacancy occurs.

Willis S. Home, contract surgeon, former orders revoked; he is relieved from further duty in the Division of the Philippines and assigned to temporary duty in the Department of California.

Paul C. Hutton, lieutenant and asst.-surgeon, U. S. A., leave of absence extended ten days.

Frank J. Ives, major and surgeon, U. S. A., member of a board at Fort Sheridan, Ill., to examine officers of the Army for promotion.

James P. Kimball, colonel, assistant surgeon-general, retired from active duty on account of disability incident to service, to date from April 7, 1902.

Arthur M. Line, lieutenant and asst.-surgeon, U. S. A., former orders amended so as to direct him to report for duty at Fort Riley, Kan.

James E. Meade, captain and asst.-surgeon, Vols., recently appointed and now at San Francisco, Cal., to proceed to Manila, P. I., for assignment in the Division of the Philippines.

George H. Richardson, lieutenant and asst.-surgeon, U. S. A., member of a board at Fort Grant, Ariz., to examine officers of the Army for promotion.

Charles F. Smith, contract surgeon, member of a board at Fort Sheridan, Ill., to examine officers of the Army for promotion.

William J. S. Stewart, captain and asst.-surgeon, Vols., from temporary duty at Fort Slocum, N. Y., to San Francisco, Cal., for temporary duty in the Department of California and assignment to a transport when a vacancy occurs.

Paul F. Straub, captain and asst.-surgeon, U. S. A., member of a board at Omaha, Neb., to examine officers of the Army for promotion.

Charles W. Thorp, contract surgeon, leave of absence extended for one month.

Hugo A. Wahl, contract surgeon, leave of absence for two months granted, with permission to go beyond the sea.

Charles K. Winne, lieut.-col. and deputy surgeon-general, member of a board at Omaha, Neb., to examine officers of the Army for promotion.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ending April 12, 1902:

Surgeon T. A. Berryhill, granted sick leave for six months.

Medical Inspector E. Kerchner, retired, commissioned medical inspector on the retired list from April 2, 1902.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended April 10, 1902:

Surgeon H. W. Austin, to proceed to the Delaware Breakwater and Reedy Island Quarantine Stations as inspector of unserviceable property.

Surgeon A. H. Glennan, to report at Washington, D. C., for special temporary duty.

A. A. Surgeon S. H. Hodgson, granted extension of leave of absence for ten days from March 30.

A. A. Surgeon J. M. Jackson, granted leave of absence for three days from April 9.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended April 11, 1902:

#### SMALLPOX—UNITED STATES.

California: San Francisco, March 22-29, 7 cases.

Colorado: Denver, March 22-29, 4 cases.

Illinois: Chicago, March 29-April 5, 9 cases; Danville, March 29-April 5, 3 cases; Peoria, March 1-31, 17 cases.

Indiana: Evansville, March 29-April 5, 4 cases; Indianapolis, March 29-April 5, 18 cases; Terre Haute, March 22-April 5, 1 case.

Iowa: Ottumwa, March 1-29, 32 cases.

Kentucky: Covington, March 30-April 6, 18 cases.

Louisiana: Shreveport, March 29-April 5, 14 cases.

Maryland: Baltimore, March 29-April 5, 2 cases, 1 death.

Massachusetts: Boston, March 29-April 5, 23 cases; Brockton, March 29-April 5, 2 cases; Cambridge, March 29-April 5, 3 cases, 1 death; Everett, March 29-April 5, 5 cases; Holyoke, March 15-April 5, 11 cases; Melrose, March 5-April 5, 2 cases, 1 death; New Bedford, March 29-April 5, 1 case; Newton, March 29-April 5, 3 cases; Quincy, March 29-April 5, 3 cases; Somerville, March 29-April 5, 1 case.

Michigan: Detroit, March 29-April 5, 15 cases; Ludington, March 29-April 5, 9 cases.

Nebraska: Omaha, March 29-April 5, 24 cases.

New Jersey: Camden, March 29-April 5, 4 cases; Elizabeth, March 22-29, 1 case; Newark, March 29-April 5, 20 cases, 3 deaths.

New York: New York, March 29-April 5, 75 cases, 20 deaths.

North Carolina: Charlotte, March 1-31, 30 cases, 1 death.

Ohio: Cincinnati, March 28-April 4, 13 cases, 1 death.

Pennsylvania: March 29-April 5, Altoona, 1 case; Johnstown, 1 case; Philadelphia, 26 cases, 6 deaths.

Rhode Island: Providence, March 29-April 5, 2 cases.

South Dakota: Sioux Falls, March 29-April 5, 1 case.

Tennessee: March 29-April 5, Memphis, 15 cases; Nashville, 1 case.

Utah: Salt Lake City, March 29-April 5, 1 case.

Virginia: Roanoke, March 1-31, 32 cases, 1 death.

Washington: Tacoma, March 22-30, 5 cases.

West Virginia: Wheeling, March 29-April 5, 1 case.

Wisconsin: Green Bay, March 28-April 6, 2 cases.

#### SMALLPOX—INSULAR.

Porto Rico: Ponce, March 15-22, 6 cases.

#### SMALLPOX—FOREIGN.

Belgium: Antwerp, March 15-22, 11 cases, 6 deaths.

Brazil: Rio de Janeiro, Feb. 16-March 16, 21 deaths.

Canada: Winnipeg, March 22-29, 1 case.

China: Hongkong, Feb. 16-March 1, 8 cases, 8 deaths.

Colombia: Cartagena, Feb. 15-22, 1 death.

France: Paris, March 15-22, 2 deaths.

Great Britain: Glasgow, March 22-28, 10 cases, 6 deaths; London, March 15-22, 449 cases, 53 deaths; North Shields, to March 15, 21 cases, 2 deaths; South Shields, March 15, 8 cases.

Italy: Palermo, March 8-15, 9 cases, 2 deaths.

Mexico: March 16-23, 3 cases, 2 deaths; Vera Cruz, March 15-29, 2 cases.

Russia: Moscow, March 8-15, 2 cases, 2 deaths; Odessa, March 15-22, 3 cases, 2 deaths.

Uruguay: Montevideo, Feb. 22-28, 71 cases, 5 deaths.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 16-March 16, 128 deaths.

French Guiana: Cayenne, March 27, present.

Mexico: Vera Cruz, March 15-29, 6 cases, 3 deaths.

#### CHOLERA.

China: Sheklung, March 31, sporadic; Tung Kun, March 31, sporadic.

Strait Settlements: Singapore, Feb. 15-22, 2 deaths.

#### PLAQUE.

Brazil: Pernambuco, April 4, declared infected; Rio de Janeiro, Feb. 16-March 16, 1 death.

China: Hongkong, Feb. 15-March 1, 1 case, 1 death; Tsang Shing, March 31, 20 deaths.

Japan: Nagasaki, March 12, 1 case on S. S. Taichu Maru, from Formosa.

### THE FUNCTION OF THE SOLUBLE FERMENTS OF THE BLOOD IN INTRACELLULAR DIGESTION.

ALFRED C. CROFTAN, M.D.

PHILADELPHIA.

#### METABOLISM COMPARED TO COMBUSTION.

The constituents of the food, viz., the proteids, fats, carbohydrates and salts are indifferent to oxygen outside of the animal organisms but readily combine with oxygen within the body. As a certain amount of heat is generated and a certain amount of energy liberated during the passage of the food-material through the body, the whole process has been rather crudely compared to a combustion, life to a flame and the body to a machine that burns the fuel that is fed to it. This conception is inaccurate, for it merely considers the most superficial manifestations of the life-process, the initial and the terminal stages of a most intricate process, the finer, intermediary mechanism of which we are just beginning to understand.

If we determine the quantity of oxygen inspired within a stated time-unit and the quantity of oxygen excreted (in gaseous, liquid or solid combinations) through the various emunctories of the body in the same time-unit, we will find that nearly 19 per cent. (that is, nearly one-fifth) more oxygen leaves the body than enters it in the inspired air. This can be explained only in one way, viz.: some of the oxygen (one-fifth) contained in the excreta must be derived from another source than the air we breathe and that other source can only be the food. We can go a step further and say that the oxygen present in the food must be torn out of its combinations by a process that is akin to fermentation in its broader sense, and that consists in cleavage of proteid, fat or carbohydrate molecules: this process, moreover, must occur without the intervention of free oxygen; must, in other words, be anaërobic and take place in a reducing medium.

As a matter of fact, it can be shown that the assimilation and dissimilation of food occurs in two stages. 1, an anaërobic stage, in a reducing medium in the absence of oxygen, in the interior of the cell; 2, an aërobic stage in the presence of free oxygen (hemoglobin) at the periphery of the cell, i. e., chiefly in the blood and lymph stream. Both processes, it appears, are inaugurated by the intervention of soluble, chemical, unorganized ferments that the cells secrete. So-called "vital" processes are only indirectly concerned in these metabolic changes: for the present we are still forced to use the term merely to designate the power of cells in

two directions, viz.: 1, their power to build up active, functioning protoplasm from simpler, inert compounds; 2, their power to secrete enzymes with specific properties. Much that was heretofore considered "vital" has been robbed of this dignity by recent discoveries relating to the rôle of enzymes in "intracellular digestion."

The term "intracellular digestion" is employed in contradistinction to extracellular digestion to designate those processes of digestion or destructive metabolism that occur in all the tissues of the body other than the gastro-intestinal tract—in reality it does not even exclude the processes going on in the mucosa and walls of the digestive canal, but merely those that occur in its lumen. As the material contained in the mouth, stomach and intestine is not really within the body, intracellular digestion is essentially synonymous with general metabolism.

Leaving the fate of the inorganic constituents of the food out of our consideration, we will briefly study how the molecules of proteid, fat and carbohydrate material are rent asunder by the ferments, how the smaller torn-off molecules are recombined to form new compounds, how these are again disassimilated to simpler complexes until finally some unfortunate atoms got out of their orbit, so to say, become chained to oxygen and stumble into compounds that have to be eliminated.

#### THE THEORY OF RECONVERSION.

The fermentative changes occurring within the intestinal tract are essentially physical in character, i. e., the proteids, fats and amylaceous portions of the carbohydrates are hydrolyzed to compounds that can diffuse through animal membranes. The proteids are converted to albumoses and peptones (and in very small part to amido-products), the fats to fatty acids and glycerin, the starches to soluble sugars. That this hydrolysis is merely intended to enable the entrance of the original bodies into the organism proper is manifested by the fact that in their passage through the intestinal wall they are reconverted. Within and behind the intestinal wall, i. e., in the blood of the mesenteric veins and the lacteals we never, consequently, encounter peptone or albumose but only serum-albumin; the same in all probability applies to the fats; glycerin and fatty acids being recombined to neutral fat in their passage through the intestinal wall. Whether or not the sugars enter the blood and lymph directly is not positively determined; a great portion of these sugars certainly reaches the liver as glycogen and is deposited there as such.

This process of reconversion has recently been shown to be due to enzyme-action. It appears that the same ferments that can split fat, e. g., into glycerin and fatty acids possess the power of recombining glycerin

and fatty acids to neutral fat. This process also occurs *in vitro* by the action of lipase, the ordinary fat splitting ferment of the pancreas (steapsin). The discoverers of this "reversion" process determined, moreover, that lipase is concerned in bringing about a condition of chemical equilibrium between the fat molecule (and water) and the products of its hydrolysis; in other words, that it forms a certain proportion of fatty acids and glycerin if neutral fat is present in excess, but that it is also inversely capable of forming a certain proportion of neutral fat from glycerin and fatty acids provided the latter bodies are present in excess in the solution.

The one objection to this theory is the fact that we can not identify ferments in any other way than by their manifestations; we have, moreover, no way of isolating them from the organ-extracts in which they are dissolved. It is not impossible, therefore, that pancreatic extract, or even so-called "pure" lipase contains two ferments, the one that splits fats into glycerin and fatty acids, the other that recombines the two to fat. This objection is strengthened by the observation that a ferment other than pepsin or trypsin, namely, rennet, seems capable of reconverting albumoses and peptones to coagulable albumin. If egg-albumin or fibrin are digested with artificial gastric juice (pepsin-HCl) and the albumoses and peptones that are formed removed by dialysis (a process analogous to the removal of these products from the intestine by osmosis through the intestinal wall) and if to the dilute clear solution of albumose-peptone some rennet is added, a flocculent coagulate of albumin will reappear. As rennet is a normal constituent of the gastro-intestinal mucosa, it seems probable that this ferment is concerned in the regeneration of serum-albumin from albumose-peptone.

#### DIGESTION LEUCOCYTOSIS.

The question arises, where do these processes occur? In the mucosa, the muscularis, the serosa, the lymph or blood stream? Presumptive evidence is overwhelming in favor of the supposition that the leucocytes in the blood and lymph capillaries of the intestinal wall are in some way concerned in this process (digestion-leucocytosis). We will revert to the rôle of these cells as ferment-carriers later on and show that disintegration of leucocytes, as a rule, precedes the inauguration of many fermentation processes, a disintegration that probably precedes and is accompanied by a liberation of enzymes. We will also attempt to ascertain the source and origin of the ferments that the leucocytes harbor in their interior and that they carry to any portion of the body where they are needed to establish chemical equilibrium. All the ferments are so toxic when circulating freely and are still so universally present that we can only assume that mobile cells, like the leucocytes, bear them in a harmless form through the blood and lymph-stream to their ultimate destination.

Of the food-albumin that circulates in the blood and lymph stream as serum albumin only a very small proportion is built up directly into living protoplasm. The cell protoplasm seems endowed with considerable longevity, so to speak, for only 16 to 20 gr. of cell-protoplasm die in twenty-four hours—a remarkably small proportion in an organism weighing from 70,000 to 75,000 grams (70-75 Kg.). From these figures we know that only 16 to 20 gr. of the circulating serum albumin are directly incorporated into the cell body, are endowed with life and become living protoplasm to

take the place of that moiety of protoplasm that dies and is cast off into the blood stream.

The great bulk of the albumin, fat and carbohydrate, is simply food for the cells, and the source of the energy they require. With the aid of the enzymes the cells secrete, they split the large molecules. This process occurs in two stages; the first stage is a reduction and like every reduction requires heat; the result is the formation of numerous compounds that possess greater affinity for oxygen than the original bodies; the second stage is an oxidation in which the chemical affinities are satisfied and heat is developed. The result is the formation of highly oxidized end-products that are excreted.

The whole process, then, is a vicious circle—the heat that is converted into chemical affinity is derived from the oxidative processes that satisfy the chemical affinity—once inaugurated, the process goes on indefinitely, provided sufficient potential energy is introduced with the food that can be converted into kinetic energy.

This chemism is altogether analogous to similar processes occurring in the inorganic world. In order to reduce oxid of potassium, e. g., with carbon, heat is required; the result is metallic potassium that possesses great affinity for oxygen; if potassium is oxidized again the same amount of energy is liberated that was originally required for the reduction. We need not postulate any specific "vital" force. The universal laws of the conservation of matter and of energy operate in the same way in the organic as in the inorganic world. Living plants and animals merely possess specific powers of combining and converting matter and of transmuting energy into specific forms of motion that we call vital.

It would lead us too far were we to follow the step-wise degradation of the albumin, fat and carbohydrate molecules in detail; it may suffice to study the principal products of the first anaërobic, reducing stage, and of the second aërobic, oxidizing stage, and to elucidate, as far as we are able, the ferment mechanism of these conversions.

#### ANALOGOUS PROCESSES IN BIOLOGY.

A clear insight into these processes can be gained by drawing analogies with similar bio-chemic reactions that are carried on by unicellular micro-organisms. The animal body, after all, is merely a conglomeration of numerous unicellular micro-organisms, in which each cell is a special micro-laboratory and leads an independent existence while at the same time contributing its share to the maintenance of the whole. Unicellular organisms are so small compared to complex multicellular organisms and the metabolic changes they bring about in the media they grow in are so colossal in comparison to their bulk, that we are apt to overlook the fact that these metabolic processes are merely incidental, and certainly subservient, to the biologic needs of the cells. The character of the protoplasm of bacteria and of our body cells, moreover, is different only in distribution and not in character.

As a prototype of anaërobic life, as an illustration of the first *reducing* stage of metabolism, the life processes of *tyrothrix urocephalum*, a bacterium that has its natural habitat in putrefying milk, may be studied. This germ, when grown on milk, attacks the proteids of the milk alone and leaves the fats and carbohydrates intact. If oxygen is excluded, it splits the proteid molecule; combines some of the carbon with some of the oxygen, and generates CO<sub>2</sub>; combines hydrogen with oxygen and forms water; secretes a proteolytic enzyme that converts other portions of the proteid molecule

into peptones and then into urea, fat, ammonia compounds, tyrosin, a variety of ptomaines and certain intermediary acids. This germ requires some oxygen, but it can derive it from the oxygen atoms contained in the proteid molecule—the oxygen is needed, not for the metabolic processes that are carried on by the enzyme the bacterium secretes, but for the maintenance of the scanty life-processes of the cell.

Altogether analogous processes are carried on by the cells of the animal body. If a piece of muscle is kept in a vacuum at body temperature  $\text{CO}_2$  will be developed and water will be formed. There is evidence to show that the fats and carbohydrates are not disassimilated in this first stage, but that the proteid molecule alone is attacked as in tyrothrix and that it is converted into urea, glycogen and fat, ammonia products, leukomaines and a large variety of intermediary bodies. These processes have been studied particularly in the liver, but it can readily be shown that similar processes occur in other organs of the body; it is probable that this form of activity is a universal property of all our cells.

#### INTERMEDIARY PRODUCTS ARE TRANSIENT.

During life all these intermediary products are immediately oxidized so that it is a very difficult task to detect them. In certain diseases and intoxications, however, in which the aëration of the blood is interfered with, in dyspneic states, in the agonal stage, or immediately after death when the individual cells still live although the blood no longer circulates, these products accumulate very rapidly in the tissues and can be detected there. The reducing properties, finally, of nearly all the organs of the body have been repeatedly demonstrated by coloring methods (Ehrlich) and by feeding- and injection-experiments with iodates, indigo, certain pigments, etc.

The end products of this first stage are carbon dioxide ( $\text{CO}_2$ ), water, urea, creatin, etc., on the one hand, and a large number of intermediary products on the other. The former must be considered "rests," waste products, so to say, that have to be eliminated. Many of the intermediary products travel to the liver and are there forced into new combinations: some form urea, some uric acid, etc., but the majority of the fats, carbohydrates, hydrocarbons, amido acids, together with the original fats and carbohydrates of the food undergo oxidation in the blood stream.

#### FUNCTIONS OF VARIOUS FERMENTS.

Whereas we have so far been unable to demonstrate experimentally that the cells of our body, like certain bacteria, of which tyrothrix urocephalum is the prototype, secrete enzymes that bring about the processes of proteolytic anaërobic fermentation that we have discussed, we are able to show experimentally that the second, oxidative stage of dissimilation of fats, carbohydrates, etc., is due to the action of numerous soluble ferments that are present in the blood and lymph.

If blood or lymph is allowed to flow directly into a sterile vessel and the vessel allowed to stand for a number of hours at body temperature a progressive loss of the blood sugar will be observed. Occasionally a slight increase in the titre for dextrose will be noticed during the first half hour, followed, however, by a rapid decrease during the hours following. This preliminary increase only occurs when the blood contains some glycogen, and is explained by a preliminary conversion of glycogen to dextrose.

Here, then, we see the action of two ferments, one that can convert glycogen to sugar (an amylolytic ferment), one that can destroy sugar (a glycolytic ferment). We can go still further. If we analyze the sugar that is formed from glycogen in the blood, we will find that it consists in part of maltose (a double sugar), in part of dextrose (a simple sugar). By allowing blood to flow into alcohol and leaving the coagulate that forms in contact with alcohol we destroy the power of the blood to form dextrose, and only maltose is formed from glycogen. In other words, the blood contains both a maltase and a glycase, i. e., a maltose- and a dextrose (glycose)-forming ferment, the latter being destroyed by contact with alcohol (Bial).

If chylous fat is mixed with blood or lymph and if the mixture is allowed to stand at body temperature some of the fat will be destroyed and converted into unidentified bodies (possibly fatty acids and glycerin) that, in contradistinction to fat, are in large part insoluble in ether and are dialysable.

Another ferment called oxidase is present in the blood and lymph that possesses the power of oxidizing a number of organic substances; besides, pepsin and trypsin in appreciable quantities, not to speak of the so-called fibrin-ferment, are all found in the blood and lymph.

#### ORIGIN OF FERMENTS IS OBSCURE.

The question arises, in what constituent of the blood do we find these ferments, in the serum, the red or the white blood corpuscles; where do they come from; what is their ultimate fate?

If the blood is centrifuged and serum and corpuscles examined separately, it will be found that the serum possesses neither diastatic, glycolytic, nor lipolytic properties; an extract made from the corpuscles, on the other hand, does possess these properties to a marked degree. If a piece of one of the veins of a large animal is ligated in two places and excised, then suspended in the ice chest for twenty-four hours, coagulation of the blood does not occur and under favorable conditions red corpuscles, white corpuscles and serum can be aspirated separately. It will be found that the ferment power is inherent in the white and not the red cells. When we consider in addition that the lymph possesses still greater glycolytic and lipolytic powers than the blood, when we remember the phagocytic action of the leucocytes towards all poisons (and the ferments are very toxic) we will agree that these ferments are carried by the leucocytes. As a matter of fact leucocytes possess distinct digestive powers towards bacteria. Finally, if chemotactic bodies are added to the blood that promote rapid disintegration of leucocytes, the ferment-powers of the blood are more rapidly developed—all of which seems to justify the conclusion that the ferments are carried by the leucocytes and that disintegration of leucocytes must precede the liberation of the ferments.

Some investigators claim to have found the ferments in the serum, and as a matter of fact they are frequently there—but only after the leucocytes have begun to degenerate, an accident that can hardly be avoided when the blood is subjected to such manipulations as defibrination, centrifugation, etc. The origin of these blood ferments is obscure: there are three possibilities. They can either be formed in the leucocytes themselves, they can be formed in all or many of the tissues and organs of the body, i. e., by protoplasm in general, or they can be derived from internal secretions of the digestive glands. It is altogether impossible at present

to decide this question. In view, however, of the tendency to specialization that becomes operative in any large congregation of individual cells, the latter view is the most plausible—the digestive glands would then furnish enzymes both for extra- and intra-cellular digestion.

#### FINAL DESTINATION OF FERMENTS.

Whether the blood ferments after they perform their function are destroyed, eliminated, re-inclosed in leucocytes, arrested in the digestive glands to be re-excreted, or finally are held by such dis-intoxicating organs as the suprarenals, the thyroid and the liver it is impossible to say. As the urine nearly always contains some of the ferments, as they are nearly always present in the liver, and as they certainly must suffer the ultimate fate of all the other constituents of the body, it is probable that all these processes can and do occur.

It has been objected that the ferments are present in such minute quantities in the blood that they can not possibly be credited with an important rôle in intra-cellular digestion; but this objection is invalid. In the first place they are present in minimal quantities in the extracts we prepare because they are not intended to be present in large quantities at any time nor to be copiously excreted like the digestive ferments. When we prepare our extracts we destroy the cells and force the ferments into solution; besides, we work with small quantities of blood and consequently very small numbers of leucocytes. In studying the action of such an extract, moreover, we see only a small portion of the power that would have been expended had the cells remained intact, had the blood remained alive. I can best illustrate this by comparing the action of the ferment extracted out of a kilo of yeast-cells and the action of a kilo of living yeast-cells. The ferment solution will develop less power by far than the living cells, as in the latter new ferment is continuously being formed; in other words, the action of the ferment accumulating during an hour is only a small proportion of the hourly action of the cells. The ferment solutions from the blood only contain the remnant that is not utilized during life.

Furthermore, nearly all ferment extracts from the blood are made after defibrination or alcohol-coagulation, and it is a well-known fact that fibrin and coagulates retain ferments with a tenacity that makes it almost impossible to separate the two—in this way, too, a large proportion is lost.

From very recent investigations it appears that the ferments are chemically (if they are chemical entities at all!) nucleo-proteids, i. e., derivatives of the cell-nuclei. They are in general so akin to protoplasm both in their chemical reactions and their behavior to various physical and chemical agencies that they must be considered closely related to living protoplasm. As a matter of fact all protoplasm has some ferment-power—ferments seem to be fragments of protoplasm, and living protoplasm can do all that ferments can do and more besides in other directions, viz., it has the power of regeneration (see above) and of "assimilation."

#### REGENERATION OF PEPSIN BY FIBRIN.

Some investigations that I am at present engaged in seem to point to a still closer connection between ferments and living protoplasm even in its most "vital" properties. If 0.01 gr. of pepsin is dissolved in 95 c.c. of 2.75 per cent. HCl and 5 gr. of fibrin or egg-albumin

added, the fibrin will be digested within twenty-four hours and the fluid will become clear; of this fluid 10 c.c. are mixed with 85 c.c. of the HCl solution and 5 gr. of fibrin are added again; this, too, will be digested. This process of dilution can be repeated many times and the digestion of fibrin will proceed almost as rapidly as in the beginning; not until the 9th or 10th dilution will an appreciable retardation become noticeable. If we calculate the dilution, we will find that 1 part of pepsin seems capable of digesting many million parts of fibrin. If these same dilutions of pepsin solution are made without adding fibrin and permitting digestion for twenty-four hours, it will be found that no solution of the fibrin occurs after the dilution is greater than 1 to about 30,000 to 50,000. (This applies to the particular pepsin I am using). The whole process resembles a regeneration of pepsin by contact with fibrin—in other words, a growth in a suitable medium. In the absence of pabulum no growth occurs.

If these findings can be verified and amplified and extended to other ferments, they promise to carry us several steps forward into the borderland that lies between dead and living protoplasm.

### EPILEPSY, ITS ETIOLOGY, PATHOLOGY AND TREATMENT BRIEFLY CONSIDERED.\*

WILLIAM P. SPRATLING, M.D.

Medical Superintendent of the Craig Colony for Epileptics, N. Y.;  
Secretary of the National Association for the Study of  
Epilepsy and the Care and Treatment of Epileptics.

SONYEA, N. Y.

In the United States one person in every 500 suffers from epilepsy. In continental Europe the proportion is thought to be somewhat less, though this may be an error due to imperfect statistics; in England the ratio is about the same as in this country.

Epilepsy is one of the oldest diseases of which we have any record. Five centuries before Christ it was described by Greek physicians with much clinical accuracy.

It may be in the infant at birth, or develop immediately after, or its coming may be deferred until man has passed the milestone of life that marks to his credit threescore years and ten.

It comes irrespective of race, environment, occupation, social condition or position; affecting alike the poverty-stricken dweller of the tenement along with the rich who live in palaces.

American statistics show it to be slightly more common in males than in females, while European observers find the opposite true. In some the attacks may occur daily for years and yet produce only the slightest enfeeblement of any of the mental faculties, while in others a few attacks may, in a year's time, largely destroy all the faculties of the mind, producing in the end epileptic dementia. Its seizures may develop with sudden, shock-like violence, striking its victim to earth in the twinkling of an eye, or they may come and go with only the blanching of the face and a momentary void in the operations of the mind. In the same individual we may witness its manifestations hundreds of times in the space of twenty-four hours, at one period of the disease, and we may see months or even years intervene between its paroxysms at another period of the disease. It has no distinctive or pathognomonic symptom, for we find its two most prominent ones—convulsions and the impair-

\* Read before the College Medical Society, College of Physicians and Surgeons, Baltimore, Dec. 6, 1901.

ment or loss of consciousness—in many other conditions and due to many other causes. Its causes are legion and its varieties numerous.

Like insanity, we can not satisfactorily define epilepsy in terms. It is a nervous affection, generally characterized by some impairment or loss of consciousness, coincident with some impairment or loss of the power of motor coördination, with or without convulsions; the paroxysms being generally abrupt in appearance and short and variable in duration.

#### NOMENCLATURE OF SEIZURE TYPES.

As yet epilepsy has no fixed nomenclature for its various types, which leaves us free to present for your consideration two classifications; one based on symptomatology, the other, as far as possible, on etiology; and whichever is elected for use must be a matter of individual choice. The old symptomatic classification of grand mal, petit mal, psychic and Jacksonian is clear and concise and expresses all that is essential when speaking from a symptomatic standpoint only; but it is less scientific and far less valuable for purposes of study than a classification based on causes.

By grand mal we mean a fit of the most severe type, one in which both the body and the mind are profoundly affected, the entire body being convulsed and consciousness entirely lost.

By petit mal we mean a fit of the same general character as grand mal, but much less severe. In this form the faculties of the mind may be disturbed but consciousness not lost, the body being somewhat convulsed, but the patient does not necessarily fall.

By psychic epilepsy we mean that form in which the faculties of the mind suffer almost to the exclusion of the body. In this there is a discharge of nerve force in the regions of the brain that govern and control the intellectual acts, the feelings, emotions, memory and the will. When such attacks are purely mental, we refer to them as psychic epilepsy or psychical epileptic equivalents, i. e., they are equal to and take the place of epileptic convulsions of another kind. It is this form that is followed by the condition we term automatism. The individual is automatic, he acts like a machine; going about after the fit for hours and even for days, performing ordinary acts, but having no knowledge of what he is about.

By Jacksonian epilepsy we mean convulsive movements confined to one leg, one arm, one side of the face, or a single group of muscles; in reality, a mono-spasm due to a circumscribed irritative lesion affecting some part of the motor area of the brain. In this form consciousness as a rule is not lost and oftentimes it is not even disturbed, the patient in some instances being the witness, so to speak, of his own seizure. Jacksonian is a partial epilepsy only and we must be careful not to confound it with epileptiform convulsions due to an irritative lesion somewhere in the periphery and affecting the brain reflexly. Generally speaking, we may differentiate between the two by ascribing Jacksonian epilepsy to proximate causes, that is, causes acting primarily within the brain, and epileptiform convulsions to distal causes, or those acting first in other parts of the body, then on the brain, affecting that organ reflexly. But the lines that separate epileptic phenomena are of necessity loosely drawn and this must be so when we remember how intimately associated are all the parts of the body with the brain and how much more intimately associated are all the parts of the brain the one with the other. A knowledge of cerebral localization in the study of epilepsy

is an absolute necessity; for not only should we know the seat of the lesion in the brain in every type of convulsion, but we should know the form the convulsion will take, the order in which it will progress when the nervous discharge travels to contiguous areas, spreading from center to center, finally involving the entire organ. What should interest us most is the site, the primary condition, and the manner in which the fit starts, for it will be through studies of these that we will be most apt to find the cause.

These four types, then, grand mal, petit mal, psychic and Jacksonian, make up the classification based on symptomatology. Until we understand the commoner forms of epilepsy, the simpler we make our classification, based on etiology, the better. Once understanding the main forms, we may elaborate all we like.

At present I know of no better way to attempt a practical classification of this kind than to make three age periods, as follows: 1, up to the age of 20 years; 2, during adult life; 3, after the beginning of senility. Such a plan is at once simple and direct and arranged in the order of the importance of these periods, because most cases of epilepsy develop before the 20th year. Gowers says that three-fourths of them begin before then, while our own studies, based on over a thousand cases, show an even larger proportion.

Bearing in mind the fact that this is the developmental period and that transmitted defects generally come to light during this period, we group its epilepsies under two heads: primary or developmental and accidental. The latter also occurs during the adult period, but with far less frequency. Two kinds of heredity must be considered, similar and dissimilar, the former meaning the transmission of the same disease from parent to child; the latter meaning that alcoholism, insanity, tuberculosis, chorea or a kindred affection in the parent is changed in type in transmission so as to appear as epilepsy in the child. Dissimilar heredity is recognized by Moreau de Tours, Hammond, Nothnagel, Féré and others and it constitutes one of the problems that science may investigate in the future.

It is the epilepsies of the primary or developmental group that we are apt to carelessly designate as idiopathic, which means that we do not know the cause; while, as a matter of fact, a little persistent study of every case from all possible standpoints might make it hardly necessary for us to clothe our ignorance in that way. In a study of some 1100 cases of epilepsy that have come under our observation during the past six years, we found that 16 per cent. were due to similar heredity, 15 per cent. of the males and 17 per cent. of the females directly or indirectly inheriting the disease. In the same cases we found that alcoholism in the ancestors caused it in 16 per cent. of the males and 12 per cent. of the females. Insanity in the ancestors was definitely established in 7 per cent. of the males and 10 per cent. of the females. Tuberculosis existed in the family in 15 per cent. of the males and 12 per cent. of the females, making an average of 14 per cent. It seems that alcoholism in the father is more likely to produce epilepsy in the child than when the mother is alcoholic and that insanity in the mother more often causes epilepsy in the child than when the father is insane. Taking all hereditary factors together, we found either similar or dissimilar heredity to have been the cause of epilepsy in 56 per cent. of the entire number of cases studied, leaving only 44 per cent. due to other causes.

Accidental forms come next. These include the large number of cerebral palsies, amounting all-told to 117, or over 11 per cent. of the entire number of cases we studied. Other cases due to trauma—comparatively common in childhood; to accidents incidental to birth; to the poisons of specific diseases, like scarlet fever, measles, diphtheria and whooping cough; to the toxemias of intestinal origin, and to certain chemical poisons, which latter are not so active here as later in life, belong to the accidental group. We do not mean that whooping cough *per se* may cause epilepsy; but that it may produce a condition out of which convulsions may arise. Accidental forms are also met with in adult life; but they are rare as compared with the earlier period.

Primary or developmental epilepsy after 20 years is probably never met. After this age it is due to syphilis or traumatism, either of which at first produces epileptiform convulsions only; to alcoholism; to ptomain poison, and rarely to some chemical poison, like lead, which produces the so-called saturnine epilepsy. The accidents incident to maternity may cause epilepsy. The third period, marked by the beginning of senile changes, has fewer epilepsies still; those that do occur being due to arteriosclerosis; to organic heart disease; to intestinal toxemia in favorable subjects, and to traumatism. We should be loth to say that a single convulsion, occurring for the first time in an individual who had reached adult life, was epileptic. It is better not to so stigmatize the patient until the diagnosis can be made beyond doubt.

#### PATHOGENESIS OF EPILEPSY.

If we should regard epilepsy as a functional instead of an organic disease, it would be better to use the word physiology in place of pathogenesis in speaking of the histologic changes that are thought to occur at the time of a fit. But so far as we now know, both may be admissible. There is some difference of opinion as to the immediate cause of a fit and the manner in which it occurs; but the theory that finds most favor is based on the assumption that convulsions are due to sudden discharges of nerve force in the sensory-motor cells of the brain.

Inhibition is the highest faculty of the human mind, and there are reasons for believing that the sensory or angular cells in the second layer of the brain exercise a power of control over the motor cells in the layer above. When these sensory cells become weakened or destroyed, they lose their power of control and the motor cells explode; that is, they suddenly and violently give off nerve force at irregular intervals. This is true of all the epilepsies, no matter of what form or in what part of the brain they occur. It has also been thought that overproduction of nerve force by the large motor cells, together with molecular instability, causes these periodic discharges or overflows of nervous energy. If we could more closely analyze the condition of inhibitory insufficiency, or the lack of power of self-control found in these sensory cells, we would probably find them structurally incomplete, too small in capacity for the work they have to do, poorly insulated or impaired through other causes, congenital or acquired.

It will not be out of place in this connection to speak of the functional divisions of the nervous system made by Hughlings Jackson into lowest, middle and highest levels—"fit levels" they have been called. The lowest level corresponds practically with Marshall Hall's "spinal system," and includes the gray matter in the spinal cord in its upward prolongation in the brain as

far forward as the oculo-motor nucleus. The centers in the cord, like those of the other levels; are sensori-motor; they are automatic in action and control reflex acts that do not rise into consciousness, such as deglutition, respiration, intestinal peristalsis, vasomotor and cardiac action and perhaps highest of all, reflex movements of the pupils. The middle level is more complicated and less easily defined; but broadly speaking it includes the motor area of Ferrier, most of the temporo-sphenoidal lobe, the gyrus fornicatus and the inferior parietal lobe. This level is also sensori-motor in character. The centers of the highest level include the anterior or pre-frontal lobe and the posterior or occipital lobe, embracing the organs of the mind.

While these divisions are more or less anatomically distinct, functionally they bear the most intimate relationship one with the other and especially is this true of the two highest levels, located wholly within the brain. Fits that originate in one level and that are at first distinctive of that level, inasmuch as they indicate the function and kind of nervous tissue involved, almost invariably spread so as to more or less affect all the levels and it is a question as to how far we should go in a study of epilepsy based on these rather artificial divisions of the cerebro-spinal nervous system.

#### PATHOLOGY.

As yet the pathology of epilepsy is wrapped in considerable obscurity. Being a disease that affects the brain, we must examine that organ for whatever pathologic changes our present methods of investigation enable us to detect.

Marinesco and Serieux claim to have noted three specific lesions after paroxysmal discharges in uncomplicated epilepsy, as follows: 1, a partial disappearance of the tangential fibers of the cortex, the "neurons of association," so-called, and similar to lesions described in cases of general paralysis; 2, an infiltration of nerve cells by leucocytes; 3, the disappearance of the fine granules in the protoplasm of the cell substance of the cortical nerve cells. The latter are probably due to bio-chemical changes dependent on nutritive processes.

In epileptic insanity Bevan Lewis has noted changes in the cortical cells of the second layer. This change begins in the nuclei, which have a bright, refractive, spherical body of a fatty nature in the center, and which spreads until it occupies the whole cell, the cell protoplasm itself eventually showing signs of degeneration and breaking down completely.

Physiologically, it is known that the cell nucleus plays an important part in the functional activity of the cell and that its absence or impairment is a constant accompaniment of brain disturbances indicated by loss of control. The small pyramidal cells of the second layer are assumed to be mostly sensory in function and to be closely connected with the deeper cells, which are probably less sensory. It is also assumed that the cells of the upper layer exercise an inhibitory control over those of the deeper layer and, when this control is destroyed or impaired through disease, the discharge of the latter will be subject to changes in nutritive rhythm. This view, however, is substantially differed from by Gowers and Jackson. The former seems to consider epilepsy to be essentially a disease of the inhibitory fibers. He regards the tangential fibers of the gray matter, the neurons of association, to be more at fault than the cells themselves.

Still another view of the essential lesion is held by Hughlings Jackson, who believes that the presence of

epilepsy may be explained on the basis of increased nutrition, which in turn causes exaltation of function, issuing periodically in strong discharges. Primarily, Jackson thinks the fault is an arterial or venous one and only secondarily nervous and then due to vascular changes. He seems to imply that the true pathologic cause is to be sought in nutritive disturbances probably caused by a change in the circulation due to the occlusion of a vessel in the arterio-cortical area, which is capable of giving rise to a discharging lesion.

When death is due to status epilepticus, there is an intense congestion of all the viscera, and especially of the brain. Macroscopically, the veins and sinuses are deeply engorged, meninges injected, the white substance of the brain filled with punctiform hemorrhages and the gray matter darker or slightly pinkish in color. We are unable, however, at this time to say how far these grosser pathologic conditions may be the result instead of the cause of epilepsy.

#### THE COURSE AND PROGNOSIS.

Epilepsy tends to shorten life. Any epileptic may die suddenly at any time. I am of the opinion that more epileptics die as the result of a single fit than is generally supposed. When death comes suddenly, it is due to asphyxia, caused by the severe and prolonged contractions of the muscles about the throat and chest.

The gravest danger to which epileptics are exposed is the condition we term status epilepticus, which is likely to develop in any form of epilepsy at any time, and it is the cause of death in about 25 per cent. of all fatal cases. Epileptics are also especially prone to diseases of the heart and lungs. In 95 deaths at the Craig Colony, occurring in 6 years, 24 per cent. of them were from pulmonary tuberculosis, 10 per cent. from organic diseases of the heart and 8 per cent. from pneumonia.

Under proper treatment, that is, under conditions that enable us to absolutely control all the habits of the patient, from 8 per cent. to 10 per cent., if taken in time and treated long enough, may be made to recover.

The most discouraging symptom in the course of the disease is seen when it affects the mind and those most apt to suffer in this way inherited the epilepsy or a strong predisposition to it. The forms of mental impairment are numerous and include feeble-mindedness, imbecility, idiocy and various forms of insanity, some of them stable and some not. Most epileptics who become permanently insane have epileptic dementia. Delusional insanity in epilepsy is rare, but some form of mental impairment may be looked for in fully 90 per cent. of all cases in which the disease has existed some years.

In Jacksonian epilepsy, where the convulsions are mostly confined to the motor portions of the brain, the individual may live to old age and have a fairly good mind to the end.

#### THE EPILEPTIC AURA.

The word "aura" signifies "breath," and it is defined as a "sensation like a gentle current of air rising from the limbs or body to the head, a frequent forerunner of an epileptic attack." It is also applied to "any slight symptom preceding an attack of any disease or paroxysm"; but it is most commonly applied to the great variety of sensations that epileptics experience just before a seizure. The aura is really a symptom, a part of the fit and bears the same relationship to the convulsion that convulsions do to the disease, for the convulsion is not the disease, but a symptom only.

We may give the most common forms of aura, regional

classifications, according to their anatomical location in the body. Thus, those from the abdominal and chest cavities are either epigastric, laryngeal or cardiac, the two former being closely associated and probably due to the same cause. The auras of the special senses, including gustatory, meaning a peculiar taste in the mouth; auditory, a buzzing or ringing in the ears; visual, including flashes of light or of various colors passing in succession before the eyes; olfactory, the smelling of unusual odors; cephalic, such as giddiness and headaches; and psychic, including disturbances of the emotions, dreamy states, etc. You will meet with many anomalies in these forms and occasionally see others of a rare nature. The epigastric aura is the most common of all, occurring in about 20 per cent. of all cases, and is due, Merciere thinks, to the fact that in primordial life the stomach and epigastrium was the earliest and most important seat of pain and pleasure.

A close study of the auras is important, for they probably indicate the seat of the irritative lesion that produces the convulsion, or the seat in the brain of the primary discharge of nerve force.

#### DIAGNOSIS.

In making a diagnosis, you will ordinarily have but little trouble, if you are able to see the patient while in a seizure; without this, errors are always possible.

The convulsions of hysteria closely resemble epilepsy and certain toxic and symptomatic convulsions may be mistaken for epilepsy. Hysterical patients do not bite the tongue nor fall regardless of injury; while they exhibit the most violent muscular contractions, they are yet coördinate, i. e., they throw themselves about, kicking and striking and rolling over and do not have tonic followed by clonic muscular spasms common to epilepsy. Sometimes we find epileptic and hysterical convulsions in the same individual, attacks of one kind alternating with the other.

We found on studying the temperature laws of epilepsy, based on 1000 observations, that a rise of temperature follows about 55 per cent. of all attacks, the temperature going highest, as a rule, after grand mal seizures, in which muscular contractions were greatest; but also going sometimes up to 102 or over, in petit mal and psychic attacks, probably indicating in the latter case the disturbance of the thermal centers in the brain. Bourneville has said that the temperature is augmented after every seizure, but our observations do not agree with those of this distinguished physician. Hysterical convulsions rarely give rise to temperature elevation, and the thermometer may be of value in making a diagnosis between convulsions due to hysteria and those of genuine epilepsy.

#### TREATMENT.

The treatment of epilepsy demands that the epileptic and his disease be considered as a unit and treated as such. If we neglect one, it must be at the expense of the best interests of the other.

Forms of treatment must vary to meet individual requirements, and to do this we group them under four heads: Medical, surgical, dietetic and moral. The first three may be employed successfully by every physician and so may the fourth, where the patient is so placed as to be under the physician's full control.

The first thing a patient will look for, after coming under your care, will be a reduction in the frequency and severity of his attacks and you can best gratify him in this respect by putting him on some anti-spasmodic. Among these may be mentioned camphor, opium and its

derivatives, valerian and belladonna. The opium-bromid treatment of Fleschig, popular a few years ago, is valuable in some cases. It consists in the administration of opium for six weeks, beginning with one-half to a grain three times a day, increasing up to 10 to 15 grains a day, when it is suddenly stopped and bromid given in doses of 90 to 120 grains a day. Codein may be substituted for opium. Bechterew used the bromids in conjunction with adonis vernalis with gratifying results, finding the latter better than digitalis, which it resembles. Simulo, a South American plant of the hyssop family, has been found useful in certain cases. It is given in the form of the tincture, 5i to 5ii at a dose.

Bromipin, a brominized oil of sesamum, has lately come into use and is a good substitute for the bromids. It is a heavy oil and in some cases you may find it difficult of digestion. It is best given in the form of an emulsion, which makes it more palatable and which is prepared as follows:

|                                      |        |
|--------------------------------------|--------|
| R. Bromipin .....                    | 4 oz.  |
| Simple syrup. ....                   | 4 oz.  |
| Spts. peppermint .....               | 4 dr.  |
| Mucilage acacia, enough to make..... | 16 oz. |

Of this the dose is one to two or three tablespoonfuls three times a day, an hour or so after meals.

Its advantages are many. It does not produce the disfiguring bromic acne and, given in the form of an emulsion, it is nutritious, generally increasing the weight, making it especially valuable in feeble and esthenic cases. It may be used hypodermically in status patients, without producing local abscess like that following the hypodermic use of the bromid salts. One disadvantage of its use at the present time is its cost, being about five times that of the bromids.

If you use the bromid salts, you will get better results by the hypochlorization method, i. e., withdrawing all sodium chlorid from the patient's food and salting it with the bromid of sodium. By this you will greatly enhance the action of the bromid, 10 or 15 grains of the sodium salt given in this way being equal to 30 or 40 given in the ordinary manner.

If you have a case of status to treat, the best formula for stopping the attacks is the following:

|                               |       |
|-------------------------------|-------|
| R. Potassium bromid .....     | 2 oz. |
| Chloral hydrate .....         | 5 dr. |
| Morphia sulphate .....        | 2 gr. |
| Tincture opii deodorata ..... | 60 m. |

Add enough water to make 16 oz. and give the patient one oz. after he has had six attacks in rapid succession. If the first dose is not effective, it may be repeated in two hours.

The epilepsies due to self-intoxication call for special treatment and it is important that we regulate the diet of such patients as promptly as possible, for the intoxication comes from putrefactive changes in the alimentary canal. Beta-naphthol or salol in 5 gr. doses are useful in overcoming conditions of intestinal toxemia. In some cases the thyroid extract can be used to advantage, and the best results from its use have come from cases in which there were evidences of arrested mental development. I have seen marked improvement follow its use in the higher grades of idiocy.

The dietetic treatment of epilepsy is no less important than its medical. We can not specify in this brief paper all the food articles prohibited or allowed, no more than we can mention all the drugs that are of value, and it must suffice to say that all rich foods, such as pies, pastry, cake, things fried in grease or highly seasoned, as well as pork, veal and cabbage, should be proscribed.

the dietetic principle being that the epileptic should live on the lightest and most nutritious foods obtainable, including milk, eggs, cereals thoroughly cooked, and fruits. Of meats he should eat sparingly, then take beef, lamb, chicken, fish or game, and then only at noon. The evening meal should always be light.

As to the benefits of surgical intervention, our experience does not enable us to take a very hopeful view. In a study of over forty cases that were trephined, four of which were done at the Colony by Dr. E. A. Sharp, second assistant physician, there was no permanent benefit in any case. Some went for several months after the operation without a seizure; but in every case they eventually came back. The chief fault we have to find with such operations, when done for injuries to the brain, is that they are delayed too long after the receipt of the injury. In the meantime, the epileptic habit has become firmly established. If the injury is recent and clearly causes the convulsion, we should operate. If it is old and we are in doubt as to the advantages of an operation, it may be well to operate in some cases any way, both for the temporary benefit the patient may enjoy and for the gratification it will give the patient and his friends. But before doing the operation, make every possible effort to exclude heredity as a cause of the disease and be sure that convulsions did not exist before the infliction of the injury.

The moral treatment of the epileptic is urged because he is so often the victim of a vitiated stamina, acquired as a heritage, which makes him need a power other than his own to help him overcome his unfortunate condition.

Because of his disease he is exiled from society; denied the acquisition of trades, when his affliction comes in youth; and is kept from the public schools; the use and enjoyment of all of which, for most epileptics and to some degree, is essential for his welfare. Since his malady denies him the right to make use of all these things, and since, as such things ordinarily exist, they are not in the best form for his use, special institutions, in the way of colonies properly designed and constructed, should be created for him.

## BLACKWATER (HEMOGLOBINURIC) FEVER, WITH A REPORT OF TWO FATAL CASES OCCURRING IN THE U. S. A. MILITARY HOSPITALS AT MANILA, P. I.\*

JOSEPH J. CURRY, M.D.

Captain and Assistant-Surgeon, U. S. Vols.; Member of the Board of United States Army Medical Officers Appointed to Investigate the Diseases of the Philippine Islands.

[From the Army Pathological Laboratory, Manila, P. I.]

CASE 1.—Charles E. B., private, H Company, 12th U. S. Infantry; age, 27; service, 3½ years; born in Pennsylvania; admitted to First Reserve Hospital, Manila, P. I., 5 p. m., Nov. 9, 1901.

History: Arrived in Philippine Islands with troops March, 1899; was in good health at this time and remained so until January, 1901, when he had chills and fever of moderate severity, which were controlled by quinin. He has had no chills or fever for some months.

Present Illness: This man was performing duty up to within two days of admission to the First Reserve Hospital. He came from Tarlac, Luzon, November 9 (the day of admission to hospital) to await transportation to the United States, time of service drawing to a close. The corporal who brought him to the hospital states that patient was slightly jaundiced at time of leaving Tarlac. Jaundice increased on way to Manila; he passed "bloody" urine twice on way to hospital. Further history obtained through Asst.-Surgeon Me-

\* Paper read before the Army Medical Lyceum, Dec. 3, 1901, at Manila, P. I.

Andrews: patient had chill at Tarlac, November 7 (two days before admission). I saw the case one hour after he arrived in the hospital, 6 p. m., November 9, through the courtesy of Dr. Beal, Asst.-Surgeon, U. S. A.

The man was markedly jaundiced at this time, the sclerae of a deep, yellow color and skin of the same hue. He was conscious.

Patient, nervous, with anxious expression, stated that he had had no chill or fever, save that two days ago, for a number of months, and that he had been "doing duty" up to the day before leaving Tarlac. He started for Manila, not to go into hospital, but to await transportation to the United States. After getting on train (Tarlac is about 60 miles from Manila, on Manila and Dagupan R.R.), he felt worse, and on journey passed "bloody" urine twice. He had taken 24 grs. of quinin sulphate in capsules since chill (two days ago). He describes his urine as dark red-brown. He states that he passed bloody urine after chill before he took quinin. Temperature at time I saw him, 6 p. m., November 9, was 101.5. Fresh blood examination made in ward at this time was negative for malarial parasites; there was, however, considerable of a leucytosis, as shown by the presence of one or more leucocytes in each microscopic field (1/12 obj., No. 1 oc.) He had not passed much urine. Dried blood films were made; these stained by eosin and methylene blue. A careful search was made for malarial parasites in the stained specimens, but none were found.

November 10: Patient spent a bad night; did not sleep; vomited frequently clear, greenish fluid; bowels moved three times; stools loose and contained much blood; there was a constant dripping of bloody urine from urethra during night; he was catheterized at 11 p. m. and 4 c.c. dark, chocolate-red urine withdrawn (which was sent to Army Pathological Laboratory for examination).

On the evening of the 9th, shortly after admission, he was given a 1/30 gr. strychn. sulphate subcutan., and quinin hydrochlor., 0.65 gm. subcutan. every hour for 4 doses (i. e., 2.60 gms., 40 grs., of quinin given subcutan. the night of admission). He remained delirious the greater part of the time until death. His temperature at 10 a. m. was 99.4; pulse, 104; respiration, 20; at 4 p. m., 101.5, 120 and 26 respectively. Pulse was very weak at 3 p. m., and patient had convulsion. Nitroglycerin subcutan. and strychn. sulph. given subcutan. with slight effect. Patient had another convulsion at 5:30 p. m., and died at 6 p. m.

Urine examination: Quantity about 4 c.c.; reaction slightly acid; color dark smoky; albumin approx. .25 per cent. by weight; sediment considerable in amount, brownish in color and microscopically is made up chiefly of a brownish granular detritus; there were many brown granular casts and an occasional red blood cell. Test for hemoglobin positive, hematin crystals obtained.

*Autopsy Record.*—Body that of a man apparently between 25 and 30 years of age, well developed and well nourished; rigor mortis marked; marked general icterus; subcutaneous fat normal in amount, and icteric.

Few pleuritic adhesions, both lungs adhering to costal pleurae; right lung shows some edema throughout, left only slightly so.

Heart, weight, 345 gms.; muscle pale and flabby; valves and cavities normal.

Liver, weight, 1880 gms.; slightly enlarged, pale, swollen and brownish-yellow in color; on section blood vessels engorged; no pigmentation of organ.

Spleen, weight, 450 gms.; markedly enlarged; soft, dark chocolate in color, pulp much increased.

Kidneys, weight, combined, 330 gms.; dark-red in color; on section cortex is swollen and markings of kidney obscured by intense congestion.

Bladder was empty; apparently normal.

Blood of spleen and liver negative for malarial parasites. Cultures negative, save for colon bacillus, after 4½ days.

*Anatomical Diagnosis:* Direct and immediate cause of death acute nephritis; hemoglobinuria; acute hepatitis; general

icterus; acute splenic tumor. Indirect and determining cause undetermined.

*CASE 2.*—Charles T., civilian, had served as a private in A Company, 24th Infantry, up to August, when he was discharged, term of enlistment having expired. Up to recently he was employed as teamster, Q. M. D. (Admitted to Hospital 3, November 7.)

*Past History:* He has been in the Philippine Islands since arrival with 24th Infantry, in June, 1899. He had (malarial) fever in northern Luzon, November, 1900. No chills or fever since then, up to day before admission, when he had slight chill, followed by fever and profuse sweating; vomited frequently and had severe pains in right side, hip and shoulder. After chill passed dark "blackberry" colored urine. He came in with temperature of 98.8. Soon after admission vomited considerable greenish, bile-stained fluid.

November 7: Blood examination for malaria was negative. Urine examination gave sp. gr. 1.015; red-brown color; acid.

Blood count showed: red cells, 1,900,000; white cells, 22,000. Urine: sp. gr. 1.007; color, smoky; albumin, trace; sugar, negative; acid, reaction; microscopic examination shows specimen to be filled with a brownish granular detritus; there were many brown granular casts and an occasional decolorized red-blood corpuscle.

November 11: Urine, sp. gr. 1.011; smoky; albumin, .5 per cent.; sugar, negative; sediment, practically same as last sample, an occasional blood cell, much brown granular detritus and moderate number of brown, granular casts; test of urine for hemoglobin positive. Examination for malaria repeated every day (no quinin given) was negative for parasites in both fresh and stained specimens.

November 11, treatment had been directed toward producing diaphoresis and flow of urine; hot packs; saline cathartics and stimulation by nitroglycerin. Patient passed but little urine, and this of a smoky to dark chocolate color. Patient died at 11:40 a. m. Clinical diagnosis: Acute parenchymatous nephritis; uremia.

*Autopsy Record.*—Autopsy 3½ hours after death, by Capt. J. J. Curry, asst.-surgeon, U. S. V.

*General appearance:* Body that of a colored man, apparently 27 years of age, medium height, well nourished; conjunctivae and mucous membranes moderately jaundiced.

Lungs bound to costal pleurae by easily broken adhesions; otherwise, apparently normal. Heart is normal in size, muscle pale and flabby, valves and cavities normal.

Liver is much enlarged, pale-yellow in color; on section pale, yellowish and cloudy; capsule covered with a thin, fibrous exudate. Gall-bladder moderately distended with a viscid, dark-brown bile. No pigmentation of liver. Spleen is moderately enlarged; firm; no pigmentation. Kidneys are enlarged, firm and of a yellowish tint; contain numerous, punctate subcapsular hemorrhages; on section substance is acutely congested and contains numerous hemorrhagic infarcts. Appearance like subacute kidney on which acute process is implanted.

Stomach is normal; contains a small amount of yellow, bile-stained mucus.

Intestines are apparently normal.

*Postmortem Microscopic Findings:* Blood and pulp from spleen and kidneys negative for malarial parasite. Cultures negative; no growth after 4½ days.

*Anatomical Diagnosis:* Direct and immediate cause of death, hemoglobinuria; acute nephritis; acute hepatitis; general icterus; acute splenic tumor. Indirect and determining cause undetermined.

Hemoglobinuric, or blackwater fever, was first described by French naval surgeons stationed off the north-west coast of Madagascar (Manson). These names are applied to a fever, generally spoken of as non-contagious, which is characterized by the presence of hemoglobin in the urine, and by a marked jaundice. This same condition has also been reported under the names, "bilious remittent fever" and "West African fever." Many investigators in the field of tropical medicine regard it

to be of malarial origin. Koch and others, however, believe that blackwater fever arises from other cause or causes than malaria.

These terms, blackwater fever, hemoglobinuric fever, etc., describe but one symptom, which symptom may occur in a number of conditions. Therefore it is not to be wondered at that such a wide difference of opinion should exist among investigators. Blood pigment in the urine occurs not only in the course of malarial fever, but it may also occur in a number of septic, or toxic fevers. It occurs in rheumatic, typhoid and typhus fevers, and in scarlet fever; also, in yellow fever, and in poisoning by phosphorus and some other chemicals.

It is well to bear in mind all this as well as the fact that, in the tropics there has, up to very recently, been but little scientific or accurate work done in study on the etiology of disease.

The word "malaria," too, has been much abused in the tropics, as it has been elsewhere. While the malarial fevers are very common in the tropics—one of the two most common diseases (dysentery the second in frequency) occurring in the Philippines as shown by sick report—still there are many other diseases of frequent occurrence. We meet here a large proportion of the various diseases found in temperate zones, and in addition there are many unrecognized and imperfectly described conditions.

There is a tendency among many tropical disease authorities to make "malaria" responsible for the great lion's share of all ailments. It is undoubtedly responsible for the majority of ailments in many tropical districts, but this does not apply by any means to all the tropics. It certainly does not apply to the Philippine Islands.

In certain districts of these islands there exists the most virulent type of tropical malarial fever, but this is not the rule. The type here is generally comparatively mild, and yields readily to treatment. I believe the same holds true of many other tropical countries.

In explanation of the above remarks I wish to repeat what I have said before: that while I realize that malarial fever is a very important factor in the production of a large and serious sick report, in these islands as well as in other tropical countries, still I think that, as a rule, its importance is magnified at the expense of other very important and serious conditions. Malaria has been for years a refuge, a cloak for our ignorance. Even the best are prone to fall back on "malaria," especially here in the tropics. Truly, "malaria" covers a multitude of sins.

I have found many cases, diagnosed malarial fever here, to have tubercle bacilli in their sputum, and I have also many times found at autopsy in such cases pulmonary or general tuberculosis. We are especially liable to be too easily satisfied with the diagnosis of malaria, forgetting that many other conditions found here simulate, especially in the chronic type, the malarial fevers. Then, too, even when undoubted malarial fever exists, it is very frequently only the minor factor in producing the symptoms in the sick man.

Malarial fevers are prone to occur in men sick from other diseases, especially in diseases running a subacute or chronic course. Thus in the course of dysentery and of tuberculosis it is common. It occurs frequently in the convalescence from typhoid fever, and in the subacute or convalescent stage of Malta fever.

I have seen often men coming into the First Reserve Military Hospital (Manila, P. I.) from all parts of the

islands with diagnosis of "malaria," who had typhoid fever or dysentery and a number with acute tuberculosis. In only 9 cases out of 255 which came to autopsy at that hospital was malarial fever the primary cause of death, and in but 8 others were there evidence of chronic or recent malarial fever (pigmented organs or parasites in splenic pulp). In the same series, 10 deaths were due to pulmonary tuberculosis, 40 to typhoid fever and 98 to dysentery.

We hear but little of tuberculosis in the tropics, while it is one of the most important and fatal diseases here, ranking next, and close in fatality to dysentery, among the natives, and standing high up among the list of fatal diseases among the Americans and others of the white race. During the last 11 months we have found at the Army Laboratory, in the sputum of officers and men, tubercle bacilli in 43 cases out of a total of 237 cases examined. Most of these cases were thought to have malaria in the beginning. Tuberculosis is commonly diagnosed calentura by the native doctors, and almost as frequently "malaria" by his white confrère.

*Geographical Distribution.*—Blackwater fever is practically confined to the tropics and subtropics, though it does occur occasionally farther north, cases having been reported in Georgia and other Southern U. S. States. This fever is very common in equatorial Africa, especially on the west coast where it is well known under the name of West African Fever. Copeman mentions that on the Gold Coast (West Africa) no less than 38 per cent. of the Europeans residing in certain settlements are annually attacked with this fever. Blackwater fever also occurs in Java, New Guinea and in districts in some of the South American countries. Marchiafava and Bignami mention that it occurs in Sicily and Sardinia.

Manson reports this fever to have been observed in southern China, in parts of the Eastern Peninsula and in the Malay Archipelago; also in India. It is strange that until recently the writers on Indian diseases have never mentioned it. Manson thinks that possibly this disease is of recent introduction into India. He says: "It is difficult to believe that it could have escaped the attention of these capable and acute observers."

In general its geographical distribution corresponds with the distribution of estivo-autumnal malaria, whether in the tropics or temperate zones. Marchiafava and Bignami are responsible for the statement that it is very rare in the Roman Campagna, where estivo-autumnal fever is common.

*Etiology.*—Hemoglobinuria, as mentioned above, occurs in the course of a number of toxic and septic infections, and after poisoning by certain chemicals, as well as in malarial fevers. Marchiafava divides these hemoglobinurias into several groups. He says: "Given the imperfection of our present knowledge we are obliged to divide the hemoglobinurias occurring in malarial subjects into several groups, and as the criterion for such distinction, we take in the first place the action of quinin, and in the second place the presence or absence of the malarial parasites in the blood. In the first group he places those cases in which quinin appears to be the exciting agent of the attack—quinin hemoglobinuria. In the second group he places all cases which occur without our being able to ascribe the attack to the toxic action of quinin, and in whom active malarial parasites are present, or where the malarial fever has run its course. This class he calls "malarial hemoglobinuria." Marchiafava and Bignami say little of the hemoglobinurias other than

those of malarial origin. They point to the frequency of the occurrence of attacks of hemoglobinuria in connection with the malarial fevers, and they believe there is an intimate relation between hemoglobinuria and the estivo-autumnal infection. Marchiafava and Bignami, as well as many other investigators, fail to explain the large class of hemoglobinurias which occur without any evidence of the malarial infection. They use frequently the indefinite term "malarial influence."

There have been reported during the past few years, by competent observers in Africa and elsewhere, a number of cases of blackwater fever in which there was no evidence of a malarial infection as the cause. We have in our two cases evidence that blackwater fever does occur without any evidence (either during life or at postmortem) of a malarial infection.

*Symptoms.*—The attack of hemoglobinuria comes on suddenly without any characteristic prodromata. Generally the attack begins with a marked chill which is accompanied by more or less vomiting of green bile, the vomiting being usually severe. Following the chill in a very short time the patient voids dark smoky, or blood-colored urine. Coincidentally, or within a few hours, he becomes jaundiced, the icterus in grave cases becoming rapidly more and more marked. The degree of the icterus indicates, as a rule, the gravity of the attack. In mild cases the icterus may be slight. The attack lasts from 4 to 6 days; it may be shorter (24 hours or less), and occasionally it is prolonged beyond six days.

*Physical Examination.*—In severe cases there is marked physical depression, headache and either somnolence or delirium. Abdominal symptoms present are, tenderness on pressure in the epigastric, hypochondriac and lumbar regions, and often marked tympanites. The liver is appreciably enlarged, also the spleen. The temperature rises, as a rule, rapidly to 103, or over; exceptionally the fever does not go over 100.8. The fever then continues with irregular remissions to the end.

*Termination.*—The prolonged cases are usually grave, but exceptionally there is spontaneous recovery. Death may occur during the attack, with symptoms of cardiac paralysis. In other cases the patient falls into a coma, the urine decreases progressively in amount, and death follows a period of anuria. According to F. Plehn, thrombosis of the heart is the cause of death in the greater number of cases. Death is due in a large percentage of cases to acute nephritis and uremia.

*Urine.*—In the urine we find the characteristic data, from which the disease is named. In mild cases the urine is not diminished in amount, and may even be increased. In severe cases, however, the patient passes with considerable pain and tenesmus a small quantity of urine, 50 to 100 c.c., or even less, in 24 hours. Sometimes after a few hours of onset the renal function ceases entirely. The color of the urine varies from claret-red to almost black. Reaction is generally acid. Albumin is present in varying quantities, generally considerable in amount, from 0.25 to 0.5 per cent. by weight or more.

Spectroscopically, the bands of methemoglobin or of oxyhemoglobin are found. Marchiafava and Bignami report the occurrence of the methemoglobin in the greater percentage of cases. The sediment is usually considerable in amount, varying in color from claret-red to dark-brown. Microscopically it is made up in the greater part of a brownish or reddish yellow, granular detritus. There occurs an occasional changed red blood cell. There are but few red blood cells present and these may be entirely absent. In addition to the

mass of brownish granular material there are hyaline and granular casts, usually stained brown, renal cells, swollen and degenerated, and leucocytes.

In cases which recover, the albumin, in small amounts, persists for some days after the urine has cleared. In mild cases the hemoglobin may almost if not entirely disappear in a few hours after the beginning of the attack, and the urine resume its normal appearance.

*Treatment.*—Quinin has been given in hemoglobinuric fever on the supposition that the hemoglobinuria and fever are due to the action of the malarial parasites. Some writers, as Stendal, Kucher and others, advocate the treatment of this condition with large doses of quinin; others, among them Tomaselli, the Plehn brothers and Koch, attribute the fatal issue or the grave course in many hemoglobinuric attacks to the obstinacy of physicians in the tropics in giving quinin (Marchiafava and Bignami). These latter writers hold that the conduct of physicians in the matter of the administration of quinin should be regulated by the result of the blood examination. They say: "In cases where active malarial parasites are present in the blood during the attack, and where the hemoglobinuria comes after a succession of malarial attacks, then quinin should be given." These writers state further that "hemoglobinurias without quinin are much milder than those treated with quinin." Manson regards quinin, in this condition (blackwater fever), as comparatively useless in all cases, and that it exerts no effect in cutting short the duration of the attack. Plehn, who has had an extensive experience with blackwater fever in the Cameroons, believes that quinin in this condition tends to aggravate the hemolysis. He deprecates altogether the use of quinin during a hemoglobinuric attack. He suspends the administration of the drug during the attack, resuming it subsequently after the attack has subsided. Plehn's results are far more favorable than are those of the physicians who give heroic doses of quinin.

The treatment of hemoglobinuric fever (aside from quinin), resolves itself into the treatment of symptoms. In severe cases where vomiting is persistent, resort may be had to nutrient enemata, and to intravenous injections of normal salt solution. In uremic cases, administer diaphoretics, chloral hydrate, etc. Often cracked ice and small amounts of brandy or champagne will be retained when it is impossible to give anything else by mouth. Inhalations of chloroform are advised by Marchiafava, and some French writers, where there is agitation with cyanosis and dyspnea. Stimulants, inhalations of oxygen and the administration of opium and chloral hydrate are recommended by various writers for the same symptoms. Among other drugs advocated by various men are ergotin, methylene blue, tannic acid, sodium salicylate and arsenic.

Manson suggests if the malarial parasites are present in the blood the use of moderate doses of quinin hypodermically (5 grs. every 3 or 4 hours), preceded by a large dose of calomel. When the urine becomes much diminished in amount and tends to be suppressed, diuretics must not be given, with the idea of stimulating the kidneys, but hot fomentations to loins and plenty of bland diluents administered, and the patient put on a strict milk diet, which should be continued until all albumin has disappeared from the urine. He regards these as the only rational and safe methods of treating blackwater fever. He further states that antipyretics, as antipyrin and phenacetin, are dangerous.

Koch, as well as Plehn and others, believe that quinin is positively harmful in hemoglobinuric fever, and advises strongly against its use. Plehn, Marchiasava and Bignami, and other observers, state that the hemoglobinuric paroxysm often subsides spontaneously without treatment.

*Résumé.*—We have in our two cases the classic picture of blackwater fever as described by various writers. In both cases there was the history of previous attacks of fever with chills. Each case began suddenly, without any prodromata, with a chill followed closely with hemoglobinuria and marked icterus. We have the characteristic symptoms and the characteristic urine.

Case 1 had "chills and fever" ten months previously; he had been in these islands two years and seven months when his attack of hemoglobinuria came on. Case 2 arrived in the Philippines two years and three months ago. He had "chills and fever" one year ago.

The question is, whether the previous attacks of chills and fever in these cases were attacks of malarial fever. In the last attack (i. e., the chill and fever accompanying the hemoglobinuria), in each case we have no evidence, either during life or at postmortem, that the malarial parasites were responsible. During life repeated blood examinations were negative, and at postmortem the evidence was negative, i. e., there was neither pigmentation of organs, nor parasites in cover slips from spleen, liver and kidneys.

It might be said by some that the chills and fever in our cases, as well as the hemoglobinuria, were due to the malarial "poison"; that these are cases of "post-malarial" hemoglobinuria. This is a very unsatisfactory explanation.

In many tropical districts three-fourths of the white residents would have had malarial fever at some time during a two or more years' stay. How would it sound to call a dysentery in such individual a post-malarial diarrhea, or to call a typhoid diarrhea by the same name? Where malarial fever is so common as in the tropics, nearly all other diseases could, in a sense, be called post-malarial.

It may be possible that malarial fever does leave a poison, or to speak more clearly, may alter conditions in the body and body fluids which predisposes to, or at times brings on an attack of blackwater fever.

But if blackwater fever is a malarial or post-malarial affection, why is it that only in a very small percentage of cases of estivo-autumnal malarial fever does it occur? In the autumn of 1898, while on duty at the General Hospital at Fort Meyer, Va., I observed some 300 men of the 5th Army Corps, returned from Santiago. Many of these men had estivo-autumnal malarial fever, among them many very severe cases, but no case of blackwater fever occurred. In the Philippines the writer has seen many cases of estivo-autumnal fever among the patients in the military hospitals, and never met with a case of blackwater fever before.

Many hemoglobinurias without doubt occur during malarial paroxysms, and the malarial parasites of the estivo-autumnal type seem to be the exciting cause in such cases, but there is a large class of hemoglobinurias, of which our two cases are types, occurring in the tropics which appear to have no relation to malarial fever.

To Major R. H. Zauner, Surgeon U. S. Volunteers, I am indebted for the report of a case of hemoglobinuria following on an attack of dengue: This patient, a soldier on duty in northern Luzon, had a typical attack of dengue, with rash and all the characteristic symp-

oms. He was in the hospital for about ten days, during which time blood examinations were negative for malarial parasites. The man returned to duty in ten days. He performed duty for three days, when he returned to the hospital with moderate icterus and passing dark-red, smoky urine. No parasites were found in the blood at this time. He was given small doses of quinin and got well after a moderately severe attack. Some weeks later malarial parasites (estivo-autumnal) were found in his blood. Quinin was given in moderate dosage and the patient made a good recovery from his malarial attack, without hemoglobinuria or other noteworthy symptoms.

This case may have been a malarial hemoglobinuria. The parasites may have been present in, or before the hemoglobinuric attack, in small numbers in the peripheral circulation and have escaped detection. If so it is curious why hemoglobinuria should have accompanied the first attack and not the second, which was undoubtedly malarial and which followed the first in the course of a few weeks.

The etiology of blackwater fever is certainly obscure. We know that this fever originates most commonly, if not always in "malarious" districts, where the estivo-autumnal type is common.

On the other hand in many similar districts blackwater fever is unknown. Then again, it may occur during the course of one malarial attack in an individual, and be absent in preceding and subsequent malarial attacks in the same individual. The evidence is very strong that some other factor or influence besides that of the action of the malarial parasites is necessary to produce blackwater fever.

*Diagnosis.*—Yellow fever is probably the only disease presenting symptoms similar enough to those of blackwater fever which give any great difficulties in differentiating. The invasion of each disease is marked by somewhat similar symptoms, but after a few hours there is usually not much difficulty in making a correct diagnosis. (This all depends, however, on whether we see the case from the beginning of the disease through to the end. Given a case of either disease several days after commencement, it might be difficult for the time to make a diagnosis.) As noted above, in hemoglobinuric fever the icterus and hemoglobinuria comes on practically coincidentally, in a very short time following the initial chill.

Albuminuria always accompanies the hemoglobinuria, consequently albuminuria is one of the earliest symptoms. It appears on the first day, at the very start of the disease.

In yellow fever, on the contrary, albuminuria does not occur usually until the third day (from the second to the fourth day). The jaundice of yellow fever is not intense at the beginning, and increases as a rule gradually, especially with the secondary rise of temperature. While hematuria, and even hemoglobinuria may occur in the course of yellow fever, still this is not so very common, especially the latter, and if it does occur it is one of the later manifestations.

In yellow fever we have a most characteristic symptom described by Faget of New Orleans (Osler): "The slowing of the pulse with a steady or even a rising temperature."

The liver and spleen in blackwater fever are appreciably enlarged, while in yellow fever there is usually no noticeable enlargement of these organs. The vomit in blackwater fever consists of a greenish, bile-stained mucus, which appears early in the attack, instead of the

"coffee-ground" vomit of yellow fever. Then, too, hemoglobinuric fever is endemic and not epidemic.

It can readily be seen that under some circumstances, for instance in the field where examinations of the blood and urine can not be made, that for a time at least it might be difficult to make a diagnosis. Still, even here after a few days the difficulty would be cleared away.

Of course, the finding of active malarial parasites in the blood during the paroxysma would at once show that the attack was one of malarial hemoglobinuria.

Pathologically, postmortem, in yellow fever we have an intense fatty degeneration of the liver, and the mucous membrane of the stomach is markedly injected and contains usually blackish, changed blood. The liver in yellow fever is pale in color and friable; the spleen is soft but not much enlarged, whereas in blackwater fever there is marked enlargement of spleen and liver, and these organs are usually hyperemic.

In one of our cases, however, the liver was pale-yellow in color, not much enlarged and gave the same appearance, both macroscopically and microscopically, as yellow fever.

It is worthy of special note that the *Stegomyia fasciata*, the mosquito shown by Major-Surgeon Reed, Act. Asst. Surgeon Carroll, and others, to be the common, if not the only disseminating agent of yellow fever, occurs in large numbers in Manila and vicinity, and in many districts here in the Philippines. The writer has caught many specimens himself in the Army Laboratory, at his quarters on Calle Nozeleda, Manila, and in Hospital No. 3. Many specimens of this mosquito are found in the collections sent in to the laboratory for identification by the army surgeons from posts throughout the islands. Fortunately yellow fever has never been known in the Orient.

It is possible with out fast transports and merchant ships to bring infected mosquitoes or infected men to these islands.

The *Stegomyia fasciata*, as shown recently by Reed, will not survive longer than five days without water, and even with water under favorable conditions usually dies quickly. It must be born in mind, however, that the mosquito is capable, as shown by Reed's experiments of transmitting the disease 72 days after the insect has bitten a case of yellow fever, and that it takes much less time for steamships to make the voyage (even from New York) to the Philippines.

*Treatment of Cases.*—Case 1 had taken, according to his own statement, 24 grains of quinin in the course of the two days prior to his entrance into the hospital. At the time of his admission to the First Reserve Hospital, on November 9, he was passing small amounts of "black-berry" colored urine. He was given at once (one and one-half hours after entrance), quinin hydrochlor. grains 10 (.65 gms.) hypodermically. This same dose was repeated three times, at intervals of one hour, so that 40 grains (2.65 gms.) were given in three hours hypodermically. He was perfectly rational before treatment was begun; he was weak and depressed but his mind was clear and he answered all the questions put to him intelligently.

Soon after the first injection of quinin he became delirious. The man remained in this condition until his death, which occurred 25 hours after his entrance to the hospital—a little less than 24 hours after the first dose of quinin was administered. There was practically suppression of urine during this 24 hours; aside from the

small amount passed involuntary drippings only 4 c.c. of urine was obtained by catheter.

Case 2 had no quinin before his entrance to the hospital, and none in the hospital. He came in with the same symptoms as Case 1. His scleræ were markedly jaundiced. He passed his urine freely; there was no tendency toward suppression at first. The amount was little less than normal on the first day. The quantity of urine gradually decreased in amount. The man retained his consciousness for the first three days. He died in uremic coma on the fourth day. Autopsy showed that this man had an "old," subacute (chronic diffuse) nephritis, on which an acute process was implanted. From the course of this case it would seem that if it were not for chronic nephritis he might have recovered from the hemoglobinuric attack.

*Summary.*—Here we have one case of blackwater fever treated vigorously with quinin, and the other symptomatically without quinin. The first case went from bad to worse promptly after the first administration of quinin, the man dying in 24 hours with practically suppression of urine.

Case 2 gave promise to weather the attack, but his damaged kidneys were too much of a handicap to overcome.

Quinin in the first case was distinctly harmful. From this limited experience it would be unwise for us to draw any extreme or sweeping conclusions. Our cases are additional evidence as to the harmful effects of quinin, and go toward confirming the views of such investigators as Plehn, Koch and others.

#### CONCLUSIONS.

The part played by quinin in such cases is obscure. Whether it acts as a direct irritant on the kidneys, or on the blood itself is not clear.

Quinin acts differently in the same individual in different malarial attacks. Sometimes it apparently produces hemoglobinuria, then, in a subsequent attack, has no such action (Marchiafava). The whole question of blackwater fever needs much more investigation. At present we can only theorize as to its causation.

The relation between hemoglobinuric fever and the malarial fevers is not clear.

Quinin during a hemoglobinuric paroxysm appears to be distinctly harmful.

#### COMPARATIVE VALUES OF CYCLOPLEGICS.

C. H. BAKER, M.D.

BAY CITY, MICH.

Much that we accept as settled fact in medicine has been received from so-called authorities, and we daily put up with the annoyances and inconveniences of imperfect means or instruments for lack of the time or disposition to seek out better. Since the time of Donders, atropin has been the chief reliance of ophthalmologists as a cycloplegic, but its obvious failure as an ideal substance for this use has led many investigators to look afield for a better.

As a result we now have atropin, homatropin, scopolamin, duboisin, hyoseyamin and hyosein contending for the chief place, while cocaine, ephedrin, euphthalmin, etc., divide the honors as mydriatics.

An ideal cycloplegic should possess the following characteristics: 1. First of all, it must be safe. 2. It must be sure. 3. Its effects must be of short duration. I am assuming that we are using the drug for refraction pur-

poses only. 4. It must be prompt of action. 5. Its exhibition must consume the least possible time. 6. It must be inexpensive. 7. Its solutions must keep well.

Atropin, discovered in 1833 by Mein, and independently by Geiger and Hesse, was scientifically tested by Donders, and following his lead its use became general. It possesses but three of the qualities of an ideal cycloplegic. It is cheap, keeps fairly well in solution, and is sure. The latter quality is so well marked that it has become the standard for comparison for all its rivals.

It lamentably fails in the matter of safety, for we all know and have seen the bad results which may follow its exhibition, such as local and systemic irritation or symptoms of actual poisoning. We are especially warned of the danger of glaucoma and so marked is the tendency to the latter that we are practically debarred from its use past the age of 45 years. Neither are the effects of short duration, as a single drop of 1 per cent. solution may cause accommodative disability to last fifteen days. It is slow to act, requiring one or two days' use to bring out all latent spasm.

Homatropin, derived from atropin by the action of acids, sprung into sudden popularity because it was said to be safe and its effects passed away so rapidly. Although safer than atropin it is not free from danger. Gifford<sup>1</sup> reports a case of glaucoma with retinal hemorrhage from its use, and quotes a case from Sachs and another from Shears of the same accident.

On the question of surety there seems a great diversity of opinion. Coleman<sup>2</sup> quotes Oliver, Chisholm, Savage, Jackson, Randall, Starkey, Risley, Wood and Ayers as favorable or enthusiastic advocates of its reliability, while Stewart, Holt, Cotton, Risley, Noyes, Webster and Agnew insist equally strongly on its unreliability. One case is known to me personally in which four discs of homatropin and cocaine exhibited during two hours left the patient with ability to read No. 1 Snellen. She subsequently showed hyperopia 1.50 D. under the use of hyoscin hydrobromate.

For the matter of ease of exhibition little need be said, as efficient use of solutions requires a drop every five minutes for an hour, which is a severe tax on the time of a busy man.

In an article on "Chemistry of the Atropin Alkaloids," Pinner<sup>3</sup> claims that in the several solanaceae, atropia, hyoscyamus, datura, mandragora and anisodus, there are two alkaloidal bases, namely hyoscyamin, which by the action of alkalis is converted into atropin or inactive atroscin, and second, hyoscin identical with scopolamin. Duboisin, he says, is a mixture of hyoscin, atropin and unknown alkaloids.

Duboisin, doubtless from its mixed composition and uncertain proportions, has in the hands of several observers proved too violent and erratic to be recommended for use. It also violates the third requirement, short action, as its effects last from four to eight days.

According to Pinner<sup>4</sup> scopolamin is identical with hyoscin. Schmidt and Merck also claim identity. In the few cases I have so far tested the two simultaneously, I have the impression that scopolamin is feebler than hyoscin. I have certainly found it a trifle slower in action, and after the accommodation was suspended by hyoscin in one eye it still showed action in the fellow eye under the same strength of scopolamin.

There is also confusion between hyoscin and hyoscy-

amin, some writers using the two terms interchangeably. Merck and Schmidt claim identity between them. They are isomers, the only difference chemically being that the double salt of hyoscin and gold is less soluble than the similar salt with hyoscyamin.

An unfortunate prejudice has arisen against hyoscin and hyoscyamin on the ground of dangerous action, due, no doubt, to the use of too strong solutions, but the same might be urged against any drug of their class.

To test the relative action of atropin and hyoscin, instillations were made of 1 per cent. atropin sulphate in one eye and hyoscin hydrobromate .5 per cent. in the other simultaneously. This was done with patients who by skiascopy and subjective tests were found to have eyes approximately alike in refraction and presumably in muscular strength also.

Similar tests were made with hyoscin and scopolamin, but at present the number is too small to have scientific value except as an indication. My conclusions from these cases I have already stated.

A small pointed dropper was used and a single drop, about one-half minim, placed inside the lower lid. When possible the lid was kept on the stretch for a few seconds to allow for local absorption, but quite as often this was not practicable, and I was never able to detect any difference in the result when this was omitted. From fifty cases tested in this way the following observations and averages are drawn:

In children and light-complexioned persons, absorption goes on more rapidly; in adults, especially of darker complexion, more slowly. Mydriasis begins in from six to twelve minutes, an average of nine, for hyoscin, while atropin averaged eight minutes later.

Mydriasis was complete for hyoscin in fifteen to eighteen minutes, for atropin an average of twenty-five. Difficulty in accommodating for hyoscin commenced in fifteen to eighteen minutes, and there was complete cycloplegia in thirty to forty-eight minutes.

Difficult accommodation began under atropin in twenty-nine to thirty-five minutes, and there was complete cycloplegia only at the end of several hours.

Returning accommodation was noticed with hyoscin in six to twelve hours, complete in forty-eight to sixty hours, while with atropin there was seldom lessening of paralysis in less than four to six days, and complete return of accommodation was often delayed fifteen days.

For the sake of convenience in some cases it has been found necessary to drop hyoscin into the eyes in the afternoon and wait until the following morning to re-fract. In persons with very strong ciliary muscles and in the young, it is common to find slight evidences of accommodative effort when this has been done, rendering a second instillation necessary; otherwise a single drop suffices to secure complete cycloplegia.

The results of the use of hyoscin hydrobromate for the past fifteen years, and for eight or ten almost to the exclusion of atropin, has given me more and more confidence in it. My records show between 2500 and 3000 cases in which it was used for refracting and I have yet to see a serious bad result from its employment.

In children and light-complexioned persons, when actively absorbed, it occasionally produces flushing of the face, dryness of the fauces, a feeling of fulness in the head and some dizziness on attempting to walk, the last due, I believe, to the sudden suspension of accommodation. I formerly used 1 per cent. solution, but now the .5 per cent., with the result that the above symptoms seldom appear. There is neither pain, reddening of conjunctiva, nor congestion of choroid as sometimes follows

1. Ophthalmic Record, July, 1900.

2. Coleman: Annals of Ophthalm., January, 1893.

3. Pinner: Centralblatt f. Prakt. Augenhe., January, 1898.

4. Pinner: Loc. cit.

some of the other cycloplegics, although some patients with accommodative spasm occasionally have headache until the accommodation is totally suspended. There is rarely some drowsiness manifested also.

I am unable to find any record of cases of glaucoma following its use, and if for any reason it became necessary to use a cycloplegic in an eye liable to glaucoma, I should consider it the safest one to use.

Hyoscin therefore fulfills the first requisite of safety. At first I was accustomed to use atropin in all cases of doubt as to whether hyoscin had brought out as much latent hyperopia as from my other tests I had estimated to exist; also in all patients returning dissatisfied with glasses I had given them, or those having persisting spasm after being refracted: and in fact, in all cases that could possibly be due to incomplete cycloplegia. In no instance could I find any greater variation in the findings than want of mental acuteness in the patient, or possibly too great haste in refracting would account for, the errors favoring each about alike.

In a word, then, I have never found hyoscin to fail in showing every particle of refractive error that could be discovered with any other cycloplegic. Hyoscin, therefore, fulfills the second requirement: It is sure.

Examination of the accompanying table shows that with the possible exception of homatropin, its effects are the shortest in duration; that it is the most prompt in its action; that, as it requires only one drop, its exhibition consumes the least possible time, and for the same reason its use is inexpensive.

Lastly, its solutions have remarkable keeping qualities, as after almost three years one lot contained only a minute amount of vegetation, which was filtered out, and the filtrate used with no difference perceptible in action from that of the fresh solutions. The drug seems, indeed, to inhibit the growth of micro-organisms.

In tests of this nature great accuracy is not possible, such as the exact minute when mydriasis begins, nor indeed, is it necessary to know the particular hour when returning accommodation first shows itself, but when variations in activity are between testing an hour after exhibiting a remedy and waiting a day and a half to do so, or when the question of disability for a busy patient is between two days and a possible fifteen, then such tests possess sufficient accuracy to enable us to select the best out of the candidates for cycloplegic honors, namely hyoscin hydrobromate.

**Fatal Effects of Chloroform Following Influenza.**—William Caldwell draws attention to the importance of obtaining a history of recent influenza before the administration of anesthetics, especially chloroform; there have been many deaths from chloroform administration, especially during influenza epidemics; very suspicious cases have occurred which were clearly explained by the depressed condition of the nervous system and of the heart.—*Dental World*.

## THE SURGICAL TREATMENT OF ASCITES DUE TO CIRRHOSIS OF THE LIVER.\*

M. L. HARRIS, M.D.

PROFESSOR OF SURGERY, CHICAGO POLICLINIC.  
CHICAGO.

The surgical treatment of the ascites of cirrhosis of the liver is based upon the assumption that the ascites is due to an abnormal increase in the blood pressure in the portal radicles, which in turn is produced by the peculiar changes in the liver, causing an obstruction to the passage of the blood of the portal system to that of the general system. The portal system at one time was thought to be a closed circulation, but it has been known now for some time that a number of small anastomoses exist between some of the radicles of the portal system and those of the vena cava which permit a certain amount of the portal blood to reach the general circulation without passing through the liver. Under normal conditions the amount of portal blood thus reaching the vena cava is comparatively small, but in the presence of an obstruction to the flow of blood through the liver these anastomoses become considerably enlarged and the collateral circulation thus materially increased. This collateral circulation is also still further increased by the adhesions which often spontaneously develop between certain of the visceral and parietal surfaces. In this manner the blood pressure in the portal radicles, even in the presence of considerable obstruction to the circulation through the liver, is maintained below the point at which transudation takes place. When the obstruction to the circulation in the liver reaches a certain degree, the collateral circulation is no longer able to maintain an equilibrium in the blood pressure in the portal radicles, and the pressure thus rises to a point at which transudation takes place and ascites develops. This may be called the mechanical theory of the cause of ascites in cirrhosis of the liver. That it is not the only cause will be shown later.

Based upon this mechanical theory and in an endeavor to imitate Nature's method it occurred independently to Talma in Germany, and Morrison and Drummond in England, to increase the collateral circulation, and thus decrease the blood pressure in the portal system, by artificially inducing adhesions between certain of the abdominal viscera, namely, the liver and spleen, and the omentum and the abdominal parietes. Considerable experimentation has been done in this connection, which is of much interest both from a surgical and physiological point of view, and which it would be necessary to consider in an exhaustive treatment of this subject; but owing to the limited time at our disposal it will be necessary to pass over these points and proceed at once to the practical side of the question, and consider what has actually been accomplished thus far by the surgical treatment of this condition.

Let us, then, direct our attention to the clinical results. The first 22 cases have been collected from the literature, and arranged in tabular form by Packard and Le Conte.<sup>1</sup> These cases will not be reproduced here, and the reader is referred to their article for the details of those cases.

Since the appearance of Packard and Le Conte's article I have been able to find in the literature some additional cases, and can add four unpublished cases, two of which were operated on by myself, and one each by my colleagues, Drs. Lee and Oswald, at the Alexian

Brothers' Hospital. Brief abstracts of these cases follow. They are not arranged in chronologic order.

Commandini and Salvolini<sup>2</sup> report two cases, the details of which are not at hand. One of the cases died on the fourteenth day, while in the other no improvement followed, as rapid recurrence of the ascites occurred.

Schiassi<sup>3</sup> reports three cases:

CASE 1.—Man, age not given, with pericardial adhesions producing bi-veinous congestion of liver with cirrhosis. Ascites was marked. After operation ascites returned, but gradually disappeared as collateral circulation became established. Ascites had not returned in two years. Amelioration of symptoms considerable.

CASE 2.—Man, aged 23, was affected since age of 13 with "cirrhosis nodulaire infectieuse" accompanied with ascites, which returned after tapping. S. thinks one of the nodules of sclerosis compressed one of the larger ramifications of the portal vein, or perhaps the trunk of the vein itself after entering the liver was the seat of thrombosis. After operation ascites reformed rapidly until from the fifth to the tenth day, when the fluid leaked through the operation wound. Wound, however, cicatrized and the patient increased in weight from 54 to 66 kilograms. Some ascites remained present.

CASE 3.—Female, age not given. Cirrhosis probably of malarial origin with abundant ascites: Result of operation was not so good. S. thinks because omentum was not sutured between peritoneum and muscles, and because cirrhosis was too far advanced. Some amelioration of condition was noticed. Patient able to carry on occupation. Time of observation not stated.

Grissow<sup>4</sup> reports the following:

Female, aged 49. In May, 1899, acute ascites developed. Paracentesis abdominis was performed in June, July, and August 3, August 25, celiotomy. Nothing abnormal was found; no tuberculosis; no carcinomatosis. Abdomen was closed without doing anything. Paracentesis was done again in September, October, and twice in November. Edema of the extremities developed, the urine became scanty and the general condition bad. November 28, abdomen again opened—median incision to peritoneum, which was incised transversely and the omentum drawn through and sutured—wound closed. Peritoneum curetted to favor adhesions to small intestine. Ten days after operation abdomen began to refill, but under diuresis the fluid slowly decreased. Seven weeks after operation when reported patient was still suffering. No diagnosis was made and nothing abnormal could be felt about the liver. Grissow suggested the possibility of thrombosis of the portal vein.

Sokolow<sup>5</sup> reports a case:

Man, aged 37, had ascites for three years. Cause was not stated. Twelve liters of fluid removed by puncture. Two months later 17½ liters. Four days later celiotomy—omentofixation; one month after operation 10 liters of fluid were removed by puncture. At the end of four months ascites had disappeared. No symptoms on the part of the nervous system.

Brown<sup>6</sup> reports the following case:

Man, aged 43, had during past few years increasing symptoms of cirrhosis with ascites; required repeated tapping. General condition was rapidly deteriorating. September 2, 1899, operation was made by Dr. Tuttle; median incision six inches long. Omentum was thickened, contracted and lumpy, and adherent about umbilicus to parietal peritoneum. Veins were enlarged and distended. Round ligament was thickened and hard. Liver was small, hard, hobnailed. Spleen was twice the normal size. Surface of liver, spleen and peritoneum was rubbed vigorously with dry gauze. Omentum was sutured with catgut. Upper wound was closed. Glass drain was

passed through small incision lower down into pelvis. Drainage was profuse. After two weeks drainage nearly ceased. On 23d day glass drain was changed for smaller one; on 28th day removed entirely. November 1 both wounds were healed. January 5, 1900, four months after operation, patient felt well.

Scherwinski<sup>7</sup> had the following case:

Woman, aged 38 years, had been sick for nine months. She was not a drinker; father was an alcoholic. Omentofixation. Four months later patient felt well, except weakness continued. Nothing was said about ascites, nor about the condition of the liver.

Benissowitsch<sup>8</sup> reports two cases:

CASE 1.—Young woman, aged 22 years, drank for seven years. On account of a diagnosis of tubercular peritonitis she was twice laparotomized without benefit. Liver was enlarged, spleen small. Third operation after Talma. Two months later she was tapped, "whereupon patient felt very well."

CASE 2.—Man, aged 56 years, was drinker for thirty years; tapped twice, then operation after Talma. Patient felt well for eleven days, when heart weakness appeared and in three days more he died; no autopsy.

Jelks<sup>9</sup> reports one case:

Man, aged 56 years, when first seen, Sept. 1, 1900, had abdomen greatly distended with fluid. Treatment was for a few weeks without benefit; tapped and three gallons of fluid withdrawn. Next day, Dec. 20, 1900, operation was made. Incision four inches long midline between umbilicus and ensiform cartilage. Peritoneum was rubbed with gauze for a distance of four inches around incision. Same surface curetted with sharp curette. Surface of liver also was rubbed. Omentum was stitched to parietal peritoneum. Incision was closed without drainage; primary union. No history later than eight days after the operation.

Roberts<sup>10</sup> reports two cases:

CASE 1.—Man, aged 49 years, of temperate habits, had ascites three months standing, with jaundice. Operation was Dec. 4, 1900. Omentum was fixed to parietal peritoneum by four chromic catgut sutures, which passed through the abdominal wall. One month later there was less ascites but more dropsy. Death occurred in six weeks. A nodule taken from the omentum and examined resembled spindle-cell sarcoma.

CASE 2.—Man, aged 54 years, heavy drinker, had ascites for eight months. He was tapped eight times; emaciated and jaundiced; he had edema in both feet. Urine contained albumin and hyaline casts. November 26, 1900, he was tapped—six pints. Eight days later omentofixation was done. Two-inch incision below umbilicus was made, but omentum could not be reached. Second incision was made above umbilicus; omentum was found, pulled down and fixed with two chromic catgut stitches each side of incision, which passed through entire thickness of abdominal wall. He died next day in uremic coma. At autopsy it was found that three of the stitches had pulled out.

McArthur<sup>11</sup> reports one case:

Man, age not stated, had been hard drinker for years, and developed the characteristic hobnailed liver of the alcoholic, and was admitted to hospital Oct. 23, 1900, with abdominal effusion of large amount. He was tapped and 14 quarts of fluid removed. In the course of eight weeks he was tapped three times. Operation was made Dec. 3, 1900. Peritoneum was rubbed with dry gauze. Omentum was stitched to parietal peritoneum with four fine-silk sutures each side of incision. Wound healed without drainage. On the ninth day ascites was so marked that it was thought it would be necessary to tap, but on the tenth day the tension had diminished some, and by the end of three weeks patient had lost eleven inches at the greatest circumference. Peptones were found in patient's urine after operation, which were not there before. Patient dis-

charged from hospital feeling well. (Personal communication, January, 1902: Dr. McA. says patient is still feeling very well and there has been no recurrence of the ascites.)

Ito and Omi<sup>12</sup> report five cases:

CASE 1.—Man, aged 26 years, not a drinker, had no syphilis. Six years before, he acquired malaria in Formosa. This persistent and severe case entered hospital June 6, 1900; somewhat jaundiced. Heart and lungs were normal; abdomen was somewhat distended. Upper border of liver at fifth rib in mammillary line, lower border normal. Spleen was considerably enlarged. No ascites was demonstrable. Repeated attacks of fever occurred, but no plasmodia could be found in the blood. In July ascites was present, which increased up to October 8. At operation, liver was found nodular and somewhat hard; spleen was enlarged. Adhesions had formed between the right lobe of the liver and the parietal peritoneum near suspensory ligament, also between omentum and abdominal wall midway between ensiform cartilage and umbilicus. No other changes were found in peritoneum. The surface of the liver and spleen and the opposite-lying peritoneum were rubbed with dry gauze, the parietal peritoneum about the incision scraped with a sharp spoon, and the omentum fixed thereto with sutures. Wound was closed; no drainage. Ascites returned and attacks of fever continued at intervals until Jan. 19, 1901, when he died.

CASE 2.—Boy, 13 years old, with no hereditary trouble; had measles and diphtheria in childhood. For three years he had complained of palpitation and dyspnea on exertion, and for a year of a sense of fullness in the epigastric region. Night-sweats and gradual wasting occurred. He entered hospital Oct. 10, 1900, poorly nourished and anemic, with lymph glands of neck enlarged. Heart was normal. Pulmonary expiration prolonged over apex on right side. Liver extended from fifth-rib, mammillary line to 1 cm. below costal arch. Spleen could not be felt. No ascites was demonstrable. November 1, operation was done, same as in Case 1. Liver was slightly nodular and felt firm. Spleen was slightly enlarged. Small amount of ascites was present. November 16, he left hospital feeling better. One year later he was feeling well and ascites had not returned.

CASE 3.—Man, 53 years of age, had syphilis at 35, and malaria 6 years ago. He was a hard drinker of *sake*, an alcoholic drink made from rice. He entered hospital Nov. 7, 1900, with considerable ascites. Neither liver nor spleen could be felt. He had not been feeling well for about 3 years, but was worse in last few months. November 9 he was tapped and 5700 c.c. fluid withdrawn. November 10, operation was done under Schleich's local anesthesia with eucain B. Liver was small, hard and nodular. Spleen was slightly enlarged. Operation was same as in other cases, except a gauze drain was left in the lower part of the incision. Drain was removed next day, as the excessive flow of fluid disturbed patient. He gradually sank and died on the fifth day.

CASE 4.—Man, aged 42, acquired syphilis at age of 23 and was badly affected by it; entered hospital Jan. 20, 1901. He was poorly nourished, greatly emaciated, jaundiced; all lymph glands were enlarged. He had marked ascites. He was tapped and 6000 c.c. fluid withdrawn. February 5, operation was made under chloroform. Liver was atrophied, hard, granular. Spleen was enlarged, hyperemic. Operation was similar to previous ones. February 18, there was tapped 4500 c.c. February 27, abdomen again was much enlarged and jaundice increased, with edema of extremities. March 1, there was tapped 5600 c.c. He was tapped seven times up to June 14, and on June 20 died.

CASE 5.—Man, aged 53 years, had syphilis at 23. About one year ago began to have edema of extremities, which increased until November; then it disappeared and abdomen became enlarged. From this time on abdomen was tapped twice a month. He entered hospital March 25, 1901. March 29, operation was made under chloroform and ether narcosis. Liver was a little enlarged and contained large, unequal nodules. Whitish scar-like depressions were present between the nodules. Spleen hyperemic with uneven surface. A part of the omentum was adherent to the upper surface of the left lobe of the liver.

Operation was same as before. Death occurred on the fourth day, with subnormal temperature.

To these cases from the literature I can add the following two cases by permission of the operators. The operator of Case 1 was Dr. J. W. Oswald, at the Alexian Brothers' Hospital, Chicago.

CASE 1.—Charles H., aged 37, married, German and a hard drinker. Venereal history was denied. December, 1900, he had severe cough for some time. In April, 1901, he developed an umbilical hernia. About Oct. 1, 1901, he began to feel weak and feet swelled. He has occasionally passed a little blood at stool. Skin has recently become yellowish.

Conjunctivæ were distinctly yellow. Left pupil was not perfectly round and did not react properly to light. Harsh respiratory sounds and râles were diffusely scattered over back. Heart dullness existed above second interspace. Apex beat was in nipple line in fourth interspace. There was apical systolic murmur. Diffuse heaving pulsations of heart were visible. Veins of chest, abdomen and right leg were enlarged. Tongue was normal. Breath was of sweetish odor. Abdomen was distended. Physical findings of ascites. Liver dullness was not distinct. Umbilical hernia and hernia through left rectus two inches above umbilicus—both were easily reducible. There were external hemorrhoids. Urinalysis was negative. Operation was done Nov. 26, 1901, under ether. Incision five inches in length was made so as to include both herniæ. Hernia sacs were dissected out. Omentum was sutured with catgut to parietal peritoneum, which had been rubbed with sponges and scraped with a curette. Wound was closed without drainage. Primary union took place. December 30, 1901, three gallons of fluid were tapped. After this his strength failed quite rapidly, and he died Jan. 7, 1902.

Autopsy was made Jan. 7, 1902, by Dr. Tower.

Body generally emaciated, abdomen greatly distended. Veins marked on chest and abdomen. Large scar on abdomen from ensiform toward umbilicus. There were no pleural adhesions on the left side; slight pleural adhesions generally on the right side. Lungs were slightly congested. Pericardium and heart were negative; valves normal.

Abdomen was distended with about three gallons of clear, yellow serous fluid. Intestines were very pale. Appendix was negative; extends upward and outward and backward behind head of colon. Epigastrie, mammary, mesenteric vessels and vessels in coronary ligament and on the under surface of the diaphragm were very much enlarged. Strong adhesions containing a great many small blood vessels bind the abdominal wall, omentum, diaphragm, liver, stomach, colon (transverse) and spleen in one mass.

Liver is very small, contracted, irregular and has a rough surface. It is covered with a whitish-yellow deposit of fibrous material, which is firm and dense and irregular in thickness, being an eighth of an inch thick in some places. The liver cuts with increased resistance and has on section a brownish-yellow mottled appearance. Both kidneys are greatly enlarged, the left rather more than the right. Capsule strips easily. Cortex is thin. Pyramids are dark. Interpyramidal and pelvic tissue is increased. Section has a dull, grayish color. Spleen is enlarged and covered with a dense, white capsular deposit, similar to that on the liver, being rather thicker, reaching one-quarter of an inch in places. Connective tissue in the spleen is very much increased. The splenic tissue is unusually dark in color.

The operator of Case 2 was Dr. E. H. Lee, at the Alexian Brothers' Hospital, Chicago.

CASE 2.—Louis V., age 52, married, Belgian, storekeeper. He entered hospital Sept. 2, 1901. He smokes, and drinks all alcoholies freely. He had malaria when young, but no venereal disease. One year ago he noticed swelling of the feet, which extended first up one leg, then the other. Eight months ago abdomen began to enlarge and is now greatly distended. He has recently lost considerably in weight. No other troubles are complained of. Appetite is good.

On physical examination, lungs elicited tubulo-vesicular breathing anteriorly, and subcrepitant râles posteriorly. Heart

apex was displaced upward; sounds were distinct and normal, and pulse rapid. Superficial veins were distended. There was distinct caput Medusæ. Arteries were normal. Abdomen was filled with fluid and greatly distended. Liver and spleen were not outlinable. Urine gave sp. gr. 1006; acid reaction; urea 1.2 per cent. Albumin was present; also indican, granular casts, blood cells, leucocytes and uric acid crystals.

September 3, 1901, he was tapped; three gallons fluid. Operation was made Oct. 10, 1901, under ether, with median incision above umbilicus. Parietal peritoneum was scarified and scraped, as was also the surface of the omentum. Omentum was sutured to parietal peritoneum. Wounds were closed; primary union November 4, two gallons fluid were tapped. Patient left hospital feeling somewhat better, but gradually failed and died on the last of December, 1901.

The following two cases were operated on by the author:

CASE 1.—D. H. M., Englishman, aged 56 years, married, liveryman, was admitted to the Polyclinic Hospital March 28, 1900. Mother, one brother and two sisters died of tuberculosis. He had had most of the children's diseases. He had been quite a hard drinker of strong alcoholics for some years, with no history of syphilis. Up to a year ago patient felt comparatively well. At this time he had a severe epistaxis, which lasted three days. Vomiting also occurred, and he became very weak. He had to remain in bed three weeks. About a month later he had a similar attack, not so severe as the first. December 1, 1899, he had a third attack. About this time jaundice appeared, and two months ago his abdomen became distended. He was tapped and 11 quarts of fluid withdrawn. Since the first tapping he has been tapped eight times at intervals of about six days. Appetite is good; no vomiting. Bowels are constipated. He lost 25 pounds during the past year.

Physical examination showed jaundice quite well marked. Heart was displaced upwards, but sounds normal. Lungs were normal, except compression of lower border. Respiration was labored, accelerated, becoming dyspneic on exertion. Arterial sclerosis was marked in temporals and radials. Abdomen was so much distended with fluid that liver and spleen can not be accurately outlined. Urinalysis showed: Urine dark brown, acid; 1032; no albumin; no sugar; bile; urea 3 per cent. Leucocytes and oxalate crystals were present.

Diagnosis was cirrhosis of liver with ascites.

Operation was done March 30, 1900, by median incision above umbilicus. Omentum was found very much thickened and congested. Liver was small, hard and nodular on surface—typical hobnailed liver. Spleen was enlarged. Parietal peritoneum was scraped with scalpel and omentum stitched with catgut over as large an area as possible. Wound was closed without drainage; primary union occurred.

April 3, abdomen was so distended that it was thought best to tap to reduce tension; six and one-half quarts of fluid removed. On April 11 about five quarts were tapped. Patient felt quite well, jaundice disappearing. On April 12, he left hospital. He was able to be up and around after reaching his home, which was in a neighboring state. The ascites did not return sufficiently to require another tapping. On April 22 he suddenly became unconscious and died. At the autopsy the cause of death was found to be a large cerebral hemorrhage. The omentum was firmly adherent to the abdominal wall, and the blood vessels in the adhesions were quite large.

CASE 2.—John R., German saloonkeeper, aged 55, was admitted to Alexian Brothers' Hospital July 10, 1901. Mother died of tuberculosis. He drank on an average of from 10 to 15 glasses of beer and four to eight glasses of whisky a day. There was no history of venereal history. He had gastritis 18 years ago, but had been in fairly good health up to June, 1901, when his abdomen began to enlarge and felt tense. Some distress was noticed after eating. About July 1 the ankles began to swell, and the swelling gradually extended up the legs. The skin was slightly jaundiced, and tongue coated.

Aortic sounds were accentuated. Arteriosclerosis was very marked. Radials were so hard that it was almost impossible to feel pulse wave. Lungs were negative.

Abdomen was enlarged and greatly distended with fluid. Spleen area was enlarged. Liver was not definitely outlined on account of the ascites. Superficial veins over abdomen were enlarged. Edema of lower extremities extended up to the knees.

Diagnosis was alcoholic cirrhosis of liver. He left the hospital on July 1, and returned on October 28 feeling much worse. Oct. 31, 1901, operation was done, with median incision above umbilicus. Liver was found small, hard and distinctly hobnailed. Spleen was enlarged. Parietal peritoneum was scraped with scalpel and omentum stitched to it with catgut over as large an area as possible. Wound was closed without drainage. Primary union ensued.

He was tapped November 9, 23, and December 22, about eight quarts of fluid being removed each time. He was up and around for a time, but did not gain in strength. Bowels moved with difficulty. For some time after the operation he lay in bed and seemed rather drowsy. Urine was dark brown, acid, 1026, with no albumin, no sugar, no peptone or albumose, no casts, no blood, bile present. He gradually failed and died Dec. 25, 1901. No autopsy.

These cases, with the 22 collected and reported by Packard and Le Conte, make a total of 46 cases at our disposal for analysis. Some of the cases are so lacking in essential details as to be practically of no value. We also find that the cases cover quite a range of pathologic conditions, and are therefore not comparable. Thus, we find represented alcoholic cirrhosis with atrophy of the liver; cirrhosis with enlargement of the liver; cirrhosis due to malarial infection; changes in the liver of syphilitic origin; cirrhosis of unknown origin; cirrhosis attributed to chronic heart disease; cirrhosis of infectious origin; ascites due to chronic peritonitis; ascites probably due to tuberculous peritonitis; ascites associated with probable sarcoma of omentum, and ascites supposed to have been due to thrombosis of the vena portæ.

In some cases, complications were present, such as marked arteriosclerosis, chronic nephritis, chronic inflammatory changes in the peritoneum, etc. The cases are thus of such an heterogeneous mixture that it is almost necessary to consider each one by itself.

If we consider first the largest group, namely, alcoholic cirrhosis with atrophy, we find 23 cases. Of this number 7, or 30 per cent., died within fourteen days, 5 more died within two months, and one died at six months. Of the remainder, two were living two years after operation, no recurrence of ascites. One was living one year after operation, no recurrence of ascites. One was living, time not stated, no recurrence of ascites. One was living six months after operation, improved, trace of ascites. One was living four months after operation, improved, trace of ascites. One was living four months after operation, improved, trace of ascites. One was living three months after operation, improved, trace of ascites. One was living, time not stated, improved, trace of ascites. One was living, time not stated, unimproved.

As the object of the operation is the cure of the ascites, the result has reference to this symptom in particular. Summarizing this group we find that 30 per cent. of the cases were dead in fourteen days; 52 per cent. of the cases were dead in two months; 56 per cent. of the cases were dead in six months. Of the late deaths ascites had returned in practically all of them; 13 per cent. may be said to have recovered from the ascites at the end of a year or longer. The remaining 30 per cent. were either unimproved, had to be tapped or were reported improved with some ascites still present, but the time was so short after the operation that the improved cases could not with any justification be termed "cures."

The pathology of the remaining cases is varied, and the number so small that satisfactory grouping is not possible: One of syphilitic cirrhosis, died on the fourth day. One not stated, died on the fourth day. One of sarcoma omentum, died in six weeks. One of malarial cirrhosis, died in three months, with no improvement. One of syphilitic cirrhosis, died in four months, with no improvement. One of large, smooth, pale liver, not cirrhotic, died in nineteen months; frequent tapping was required. There were 2 cases of cirrhosis secondary to chronic peritonitis, with no improvement. The pathology of one case was not stated. One case, thrombosis vena portæ. In one case of cirrhosis of unknown origin, after cholecystotomy, ascites returned slowly. In one case, not stated, tapped in one month, there was, four months later, no ascites. In one, of malarial cirrhosis, no time stated, improvement was doubtful. In one case of cirrhosis due to infection, no time stated, ascites was still present. One case, not stated, felt well four months later. In one case of unknown origin, one year later, there was no ascites. In one of enlarged liver, with probable tuberculous peritonitis, there were three operations; two years later was well, with no ascites. One case of cirrhosis of pericardial adhesions, two years later, showed no ascites. In one case no cirrhosis, with operation for intestinal hemorrhage, hemorrhage ceased and was well two years later. One case was reported on the eighth day, too early to determine result.

In the cases unaccounted for the facts at hand were too meager to warrant any statements.

Summarizing this group of mixed cases we find that 10 per cent. were dead in four days; 25 per cent. were dead in four months. In 40 per cent. no improvement was apparent, and 10 per cent. reported too early to state result. About 15 per cent. may be said to have been "cured" of the ascites for one year or longer and 5 per cent. "cured" of intestinal hemorrhages, no ascites having been present at any time.

In considering the operation itself, we find that various methods have been employed, according to the fancy of the operator. The omentum alone has been stitched to the parietal peritoneum with catgut, silk and silk-worm-gut. The parietal peritoneum has been scarified and denuded of its endothelium by rubbing with dry gauze sponges, the use of the curette, scalpel, etc. The surface of the liver, spleen and diaphragm have been irritated, with the intention of causing more extensive adhesions. Incisions have been made longitudinally, transversely and T-shaped. The omentum has been placed in pockets between the peritoneum and the muscles and in the subcutaneous tissue, each operator thinking his particular method the best.

From the small number of cases at hand it can not be shown that the particular method employed has had any special influence in determining the result.

The experiments of Tillmans seem to demonstrate that large anastomosing blood vessels are more quickly formed when the peritoneum has been denuded of its endothelial covering by scraping with a curette or scalpel. Drainage, either tubular or capillary, does not seem to be desirable, as aside from the great annoyance to the patient the danger of infection is always present, and the results thus far do not appear to have been influenced by its use.

When we consider the clinical results, respectively the relief of ascites, that have followed the Talma operation, it can not be said that they have thus far been very flattering. One reason for this is the fact, as already

shown, that the operation has been performed in a variety of pathologic conditions, some of which precluded the possibility of a favorable result. Even if we consider only the cases of true atrophic cirrhosis of alcoholic origin, we find the results have not been as favorable by any means, as one would like to see.

In considering the reasons for this it is necessary to turn to the cause of the ascites. As stated in the preliminary remarks, the Talma operation is based on the theory that the ascites is due to an increased tension in the portal system, and is therefore a pure pressure transudation. The author is of the opinion that this view is not correct, and for the following reasons: 1. Atrophic cirrhosis may proceed to a fatal termination without the appearance of ascites. 2. Increased tension may exist in the portal system, as made manifest by gastric and intestinal hemorrhages, without the development of ascites. 3. In many cases of cirrhosis, edema of the feet and legs may precede the appearance of ascites by several weeks or even months, and in the absence of any apparent kidney disease. One of the most important reasons, however, according to the author's opinion, is the fact that in these cases of cirrhosis a chronic inflammation of the peritoneum occurs, which must contribute materially to the development of the ascites, both by increasing the amount of fluid furnished by the peritoneum and by decreasing the rate of absorption. This chronic peritonitis does not seem to have attracted the attention sufficiently of the pathologists. That it occurs in the form of a perihepatitis has long been observed, but that the process occurs practically throughout the peritoneum does not appear to have been noted.

The peritoneum covering the liver is found enormously increased in thickness, the thickness in many places equaling 3 to 4 mm. The changes consist in an extensive hyperplasia of the connective tissue with round-cell infiltration. There is also a proliferation of the endothelial cells, but this layer is often lost in the preparation. These changes are not limited to the peritoneum covering the liver, but sections taken from the parietal layer, from the mesentery of the small intestine, from various portions of the diaphragm, etc., show that the changes are quite universal throughout the peritoneum. The peritoneum covering the diaphragm is well known to be extremely active in its power of absorption. The changes herein described could scarcely fail to materially diminish this power. That the chronic peritonitis is instrumental in producing the ascites is also shown by the fact that the osmotic tension of the fluid is at times greater than the osmotic tension of the blood, indicating its inflammatory nature.

There are many other points of interest and importance in this connection, such as the toxic condition of the blood, the changes in the arteries, the state of the kidneys, etc.

What, then, may we conclude regarding the present state of the surgical treatment of ascites in cirrhosis of the liver?

1. While the increased tension in the portal system is an important factor, it is not the only one concerned in the production of ascites.

2. Talma's operation in itself is quite simple and practically devoid of danger, as the deaths have been due to complications or to the advanced stage of the disease.

3. As the chronic inflammatory changes in the peritoneum are materially instrumental in maintaining the ascites, the operation should be performed early, in a pre-ascitic stage if possible, in order that the reduction

of tension in the portal system may delay the appearance of these changes and secondarily the ascites, as long as possible.

4. In a few cases the ascites has apparently been favorably influenced by the operation, but such has not been the rule, nor does it appear that the operation has in any way modified the usual course of the disease.

## ROENTGEN RAYS IN PULMONARY DISEASE.\*

ALBERT ABRAMS, A.M., M.D.

SAN FRANCISCO, CAL.

The brief time allotted to me in this symposium permits only a hurried survey of the advanced data in lung skiascopy. The possession of an *x*-ray apparatus does no more in postulating a knowledge of skiascopy than the possession of a microscope, of microscopy. The errors perpetrated by the microscopist are no less grave than those of the skiascopist. Skill in the use of the Roentgen rays for purposes of diagnosis can only be attained by the elimination of errors and this requires much experience. One should be prepared at the outset of an examination to see nothing, so that the expectant mind does not transfer to the ocular sense a function which should be reserved for judgment. The *x*-rays have not supplanted the conventional physical signs of thoracic disease; on the contrary, the later signs have advanced in value since the advent of the former. It is my custom to initiate a clinical examination with the Roentgen rays and to corroborate or enhance their revelations by the physical methods of examination, after the same manner as we employ the low powers of our microscope for a general view of the architecture of a specimen, reserving the high objectives for detail study. The proper interpretation of an *x*-ray examination coupled with correct technique means essentially a study of chiaroscuro. This study of light and shadow effects is an elementary task only to the tyro whose celerity in diagnosis is only eclipsed by his marvelous discoveries. An *x*-ray examination is practically an autopsy conducted during life, with the advantage that the functional activity of the organs accelerates diagnosis on the principle that a clinical is often more easy of achievement than an anatomic diagnosis.

### NORMAL LUNGS.

No resistance is offered to the rays by the normal lungs. They appear on the fluorescent screen brighter during inspiration than expiration. The brightness of the lungs is, however, only a relative term and is dependent so much on the thickness of the thoracic coverings and the degree of lung inflation, that I doubt even with ingenious apparatus like the densitometer and similar instruments, whether we are able at the present time to establish standards of comparison. The apparatus in question measure the penetrating quality of the rays as much as they do the density of the tissues which they traverse.

There are certain situations in the region occupied by the lungs where shadows may normally be encountered. The most important situation is the apical regions. Here the muscles of the shoulders may cast a distinct shadow, yet the integrity of the apices may be preserved. Raising and lowering the arms will increase or diminish the area and intensity of the shadow, hence the origin of the umbra may be referred to the muscles of the shoulders. In the region corresponding to the vertebral borders of the scapulæ the muscles may cast

a linear shadow in front as well as behind, but the genesis of the umbra may be referred to its true source by noting its disappearance when the position of the scapulæ is changed. In very muscular persons, other muscles, notably the serratus magnus, may throw a shadow.

In this connection, it is specially with lung inflation that I wish to speak, for, if there is any one condition above all others which misguides us in our *x*-ray interpretation, it is this. The physiologic principles involved in respiration are not always strictly in accord with clinical observation. Some of the apodictic utterances of the physiologist have been disproved by the Roentgen rays. For instance, physiology has always taught that with each inspiration the diaphragm becomes flatter in consequence of its contraction. This is not true. When viewed in action its curve is always maintained and its excursions resemble the up and down plunging of a piston. Physiology also teaches that the lungs, even at the end of expiration, are in a stretched condition. This physiologic dictum may be true in relation to primeval man, but civilized man has so subverted primeval respiration by attire and modes of living that what is now regarded as physiologic is essentially pathologic. For many years I have sought to prove, by experimental investigations and observations that the lungs even in a state of health do not fully occupy the thoracic cage. On the contrary, there are circumscribed lung areas which yield a dulness or even a flatness on percussion, areas which I have denominated atelectatic zones. I have also shown in numerous contributions that these areas may involve a lung apex, a lung lobe, or even the entire lung. It is gratifying for me to add that these observations have been accepted by Cabot, Kernig, and others. The *x*-rays have furnished me with indisputable evidence of my contention that such atelectatic patches will cast shadows on the screen, and that the shadows thus cast are of greater area than percussion would seem to indicate, and further, that the Roentgen rays will determine the presence of such atelectatic patches which elude percussional investigation. It is chiefly as an aid to percussion that the rays are operative. A percussion blow is propagated from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  inches on the surface and to a depth of about  $2\frac{1}{2}$  inches, hence it is easy to understand why the *x*-rays supplement percussion when the object is beyond the reach of the latter method. My object in emphasizing this question is to show that a lung not distended to its physiologic capacity offers an obstacle to the transmission of the rays, and consequently the appearance on the screen of shadows. Now it is the conventional practice to interpret all shadows cast on the screen as evidence of pulmonary or pleural disease and the mistakes that are bound to occur are almost as egregious as that committed by Holme's young physician whose stethoscope lodged the spider and the couple of imprudent flies. I maintain with all seriousness that any physician who places sole reliance on shadows cast on the screen as evidence of pulmonary disease, notably phthisis, without an attempt to eliminate their probable origin, will make the diagnosis of phthisis in more than fifty per cent. of the cases coming to him for examination.

Before an *x*-ray examination of the chest is attempted an effort must be made to eliminate unemployed lung areas. As a rule, deep forced inspirations conducted before and during the examination will suffice to maintain lung distension. Very often this will not suffice and then recourse must be had to inducing what I have

\* Read before the San Francisco County Medical Society, Feb. 11, 1902.

called the lung reflex. This reflex may be discharged most effectually by directing a spray of ether over the skin of the chest in the specific region investigated. When the latter is not at command, the skin may be vigorously rubbed with the hand or a towel. The result of this expedient is a momentary lung dilatation contiguous to the irritated skin area. Not infrequently this method is not efficient and recourse must be had to the

Fig. 1.—Silhouettes of chest excursions. 1. Excursions of anterior chest wall, patient standing. 2. Excursions of anterior chest wall, patient in recumbent posture. 3. Excursions of posterior chest wall, patient standing. 4. Posterior chest wall excursions, patient in prone position.

inhalation of compressed air. Recently I have been investigating the effects of such inhalations while the rays were traversing the chest and I have noted the enormous mechanic distension of the lung alveoli by such inhalations. During an examination of the lungs,

Fig. 2.—A, c, Clavicle. 1. Area of apex in normal breathing. 2. Apical area in deep breathing. 3. Apical area after elicitation of lung reflex. B, c, Clavicle. Apical area after strapping the lower chest.

the position of the patient is of the greatest importance. I can not at this time enter into a complete discussion of this subject, but will limit myself to a simple object lesson. Only recently a young man was sent to me by a colleague for a chest examination. He had a persistent cough and above his cardiac region was a diffused patch

of dulness which was likewise evident at a similar point on the posterior surface of the chest. This dulness did not disappear after forced inspirations, nor after induction of the lung reflex, yet the absence of auscultatory signs convinced me that the patch in question was only atelectatic. An *x*-ray examination demonstrated a shadow which corresponded to the area elicited by percussion. When the patient assumed the recumbent posture, dulness was no longer in evidence and the *x*-rays in this posture showed no shadow. But when the erect

Fig. 3.—Emphysema co-existing with atelectatic zones in an individual with early phthisis. 1, 2, 3. Atelectatic zones. A, Normal line of hepatic dulness. B, The line of hepatic absolute dulness in this individual. C, Normal area of cardiac dulness, which is represented in this person by the dark area. D.

position was resumed, dulness and shadow reappeared. This object lesson prompted me to investigate the respiratory activity of the lungs contiguous to the anterior surface of the chest in different postures. By means of my stethophonometer, which enables me to gauge the intensity of respiratory as well as cardiac sounds, I elicited the important fact that, in the recumbent posture, the lungs adjacent to the anterior chest wall were twice as active as in the erect posture. I further corroborated

Fig. 4.—A, B, C, D, Points on chest indicating location of shadows. L, Location of lesion.

this auscultatory investigation by stethographic measurements with a simple method, which I here show you. By means of this ground glass inclosed in a frame, I can silhouette the chest and its excursions more perfectly than by any other method. The accompanying illustrations are from a healthy individual and show that the excursions of the anterior chest wall are greater when the patient is on his back than when standing in the erect position and similarly when he adopts the

## SKIASCOPIC TABLE OF THORACIC DISEASE.—ABRAMS.

| DISEASE.                                | X-RAY APPEARANCE.  | DIAPHRAGM.  | HEART.  | GENERAL REMARKS.  |
|---|--|---|---|---|
| Abscess of lung.                        | Site of abscess indicated by dark shadow, usually found in lower lobe of lung. Shadow may disappear when abscess cavity is emptied.<br>If involving descending arch, shadow to left of sternum and above heart; if of the ascending aorta, shadow to right of sternum. Large aneurysm may throw a shadow on both sides of sternum. Pulsation visible if sac is not too thick or filled with clots. | Excursions usually limited on affected side.<br><br>Excursions may or may not be restricted.  | No dislocation of the viscera.<br><br>Heart usually displaced downward to left. Left ventricle may be enlarged.   | If abscesses are multiple, shadows are small and diffuse.<br><br>Shadow in aneurysm of ascending aorta nearer the front chest; if of descending aorta it is near back of chest. Simple dynamic throbbing of aorta and dislocation of artery by displaced vertebrae must not be confounded with aneurysm. In aneurysm also search for pulsation and shadow in region of left scapula behind. |
| Thoracic aneurysm.                      |  |   |   | After a paroxysm, normal brightness of lungs and diaphragmatic excursions reappear unless emphysematous lung changes have become permanent.   |
| Asthma.                                 | Lungs brighter than normal and extend higher and lower in chest.   | Lies low and excursions retarded.   | Position of heart lower and moves less during inspiration than normal. Right ventricle enlarged and outlines of heart unusually clear, owing to bright lungs. | Forced breathing will dissipate shadows. Rubbing skin of chest or spraying with ether will cause shadows to disappear. (Lung reflex.)   |
| Atelectasis (collapse of the lung)      | Shadows correspond to areas of collapse. If collapse is extensive, shadows are correspondingly so. If occurring as a complication of bronchitis, shadows will appear corresponding to areas implicated.  | Excursions restricted as a rule.  | Normal.   |   |
| Bronchiectasis.                         | No shadow unless lung adjacent to bronchiectasis is solidified; then shadows are usually found in middle and lower thirds of lung posteriorly.   | If emphysema complicates affection, excursions are restricted and midriff lies low.   | The right ventricle may be enlarged as a complication. The occurrence of fibrosis may dislocate heart.  | If chest is examined before a bronchiectatic cavity is emptied by coughing, distinct shadow corresponding to cavity is evident and is superseded by a bright area when contents are expectorated.   |
| Bronchitis.                             | Normal lung brightness, but perhaps a shade less bright when free secretion is established. In latter instance diffused cloudiness is usually limited to the lower two-thirds of the lungs.  | Excursions normal unless smaller tubes are obstructed, then they are restricted. Coughing by removing secretions may restore normal excursions. | Position unchanged. In chronic cases, right ventricle may be dilated.   | In the bronchitis of influenza, a localized shadow or shadows may be caused by complicated foci of lobular pneumonia. Shadow confined to apex suggests bronchitis of tubercular origin.   |
| Broncho-pneumonia.                      | Circumscribed shadows widely scattered through the lung. Coalescence of foci of inflammation increases area of shadows. Shadows usually limited to middle and lower lobes.   | Movements very much restricted and diaphragm may be high, especially during inspiration.  | Unchanged as a rule.  | Shadows due in part to areas of lung collapse, in which instance coughing and deep breathing will cause their evanescence, but shadows caused by foci of inflammation persist.  |
| Congestion of the lungs.                | Bases of the lungs cast a faint shadow. The rest of the lungs are from temporary over-distension unusually bright.   | Midriff lies low, is not as clearly discernible as normal and shows restricted excursions.  | Position unchanged as a rule, although it may lie low. Right side of heart distended.   | If congestion be dependent on cardiac incompenstation the use of cardiac tonics will soon dissipate shadow.   |
| Emphysema.                              | Pulmonary area of increased brightness which extends higher and lower in the chest.  | Low and restricted in movements.  | Area clearly defined; lies low. Right ventricle and auricle are enlarged.   | If tuberculosis complicates emphysema, abnormal lung brightness is marked by shadows usually confined to apices.  |
| Empyema.                                | Vide, pleurisy with effusion. Displacement of the heart and liver is greater in empyema than with the same quantity of serous effusion. In pulsating form of pleurisy (usually in empyema) the heart movements transmitted to fluid may be seen as diffuse undulation if patient is motionless.  |   |   |   |
| Pericardial effusion.                   | Cardiac area enlarged, but differs from shape of mere cardiac enlargement by being rounded. Pulsations of heart no longer evident.   | In sitting posture, position of left diaphragm can not be followed so far toward median line as in health. Movements restricted.                | Cardiac area low.   | Best skiascopic view is often obtained from back when lung is not too compressed. Then the conical appearance of apex is lost. Triangular space behind heart is obliterated.  |
| Pleurisy with effusion.                 | Diffused shadow on affected side; dark area changes with position of patient. As effusion is absorbed, a lighter area increases from above downward.   | On affected side outline less defined or obliterated.   | Heart displaced to right or left side according to side affected. Liver displaced downward in large effusions only.   | Any lung visible on affected side is darker than on healthy side, owing to compression by effusion.   |
| Pneumonia (croupous).                   | Affected lobes cast dark shadows. Middle portion of lung usually affected (between second and fourth ribs).  | May be obliterated; excursions very much restricted.  | Usually enlarged on right side, and displaced toward unaffected side.   | Shadow of affected area persists until complete resolution occurs. Persistence of shadow may indicate complications or thickened pleura.  |
| Pneumothorax.                           | Affected side very bright and area of clearness increased.   | Low and shows no movement.  | Outlines clearly defined and dislocated toward unaffected side.   | The degree of dislocation of heart and liver dependent on intrapleural pressure.  |
| Pneumohydrothorax and Pneumo-pyothorax. | When patient is in sitting posture there is a very dark area below and a very light one above on the affected side. Level of dark area (fluid) rises with inspiration.   | Obliterated and no movements seen.  | Heart displaced toward unaffected side.   | The degree of dislocation of heart and liver dependent on intrapleural pressure.  |
| Subphrenic abscess (containing air).    | Dark shadow limited to lower thorax; above which is a very light area (air) and above this a slightly dark area caused by compressed lung.   | Obliterated and no movements.   | Heart displaced toward unaffected side, but not to same degree as in pneumohydrothorax.   | Level of dark area changes on change of position of patient and when patient is shaken by the shoulders splashing of fluid is observed.   |
| Tuberculosis (pulmonary).               | Apex of affected side darker than normal and area of same does not increase with inspiration. In acute military tuberculosis lung shows discrete shadows embedded in a light environment (over-distended lung). Cavities, if filled with mucus or fluid, show circumscribed shadows, but when empty appear as light areas if not surrounded by consolidated lung.                                  | Excursion very much restricted, especially on side affected.  | May be dislocated in extensive disease toward unaffected side. In chronic cases, right side enlarged.   | Progression or retrogression of lesions may be determined by repeated examinations. An apex not fully inflated may cast a shadow even in the absence of disease. (Vide atelectasis).  |

## SKIASCOPIC TABLE OF THORACIC DISEASE.—ABRAMS.

| DISEASE.       | X-RAY APPEARANCE.  | DIAPHRAGM.                                     | HEART.                                    | GENERAL REMARKS.  |
|----------------|--|--|---|---|
| <b>Tumors.</b> | Shadows are cast by intrathoracic growths. They are circumscribed as a rule and are commonly confined to the middle or upper part of chest. If they pulsate, pulsation is an up-and-down movement and not expansile as in aneurysms. | Normal, as a rule, in position and excursions. | Heart may be dislocated by large growths. | Locate site of all lesions as follows: Point x-ray tube in direction of the anterior, posterior and lateral chest walls respectively, and on these different aspects mark with pencil the location of shadow. Next determine form of chest with cyrtometer and transfer this form on paper. Connect sites of shadows as perceived on different surfaces of chest by lines, and at the intersection of the latter the lesion will be situated. |

**DISEASES OF THE DIAPHRAGM.**—In *spasm*, diaphragmatic movements are practically suspended on affected side. Suddenly diaphragm contracts and descends several inches below its normal descent. Singultus may accompany the descent, while cyanosis and dyspnea become intense (personal observation). In *paralysis*, movements of diaphragm on affected side are suspended; during inspiration, midriff rises. In *diaphragmatic pleurisy*, movements of diaphragm very much restricted or even suspended. Lungs in upper part of chest brighter than usual, owing to over-distension.

**NORMAL LUNGS** are brighter during inspiration than expiration. **AVERAGE NORMAL EXCURSION OF DIAPHRAGM** in quiet breathing:  $1\frac{1}{2}$  centimeters; between full inspiration and expiration, 6.7 cm. on the right side and about 7 cm. on the left side. In long-chested persons, diaphragm excursions are greater than in short persons with deep chests.

**WIDTH OF NORMAL HEART.**—Screen about 75 cm. from tube with target directed toward a point where median line is crossed by fourth rib. Right heart measures 3 cm. from median line, and left heart, 8.5 cm. from median line; total, 11.5 cm.

prone posture, the excursions on the posterior chest wall are greater when the body is inclined forward than in the standing posture. To demonstrate the inflation capacity of the lung apex, let me direct your attention to a fluoroscopic reproduction of the apex in a normal individual. Note the area of luminosity represented by the apex in tranquil breathing. Observe how this area is augmented after forced deep breathing and again after elicitation of the lung reflex. Observe the extraordinary increase in luminosity after strapping the lower chest, which permits of breathing in the upper chest only. A word of caution is necessary to those who are desirous of confirming the latter observation. Owing to the extraordinary respiration in the upper chest area, the clavicles by their elevation obscure the luminous apical area, hence the latter area should only be gauged when the patient practices forced expiration which will permit of a complete descent of the clavicles.

In certain thoracic situations, the pleural sac is larger than the lung volume and forms spaces known as pleural or reserve spaces. Of these different spaces, I want to direct your attention to the largest, known as the sinus phrenico-costalis, which is located at the lower outer lung border at a point where the costal passes over into the diaphragmatic pleura. This space is clearly defined when the patient leans over to one side during the x-ray examination. It is at this point that we can best observe the play of the diaphragm and the condition of the pleura and the picture is tantamount to an x-ray dissection. First we note the coverings of the thorax, then the ribs and then the pleura. The normal condition of the latter is evidenced by the negative results of the examination in other words, if there are no pleural adhesions nor pleural thickening we see nothing. This situation is the best as far as my observations go for studying pleural disease.

## PRECARDIAL AND RETROCARDIAL REGIONS.

In front of and behind the heart are two important regions which have not received the attention they deserve in the thoracic disease. They are best seen when the rays are directed through the chest from side to side. They correspond respectively to the anterior and posterior mediastina. Growths and enlarged glands in the former space may be determined, whereas in the latter region disease of many important structures like the trachea, bronchi, esophagus and bronchial glands are possibly of early detection.

## EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.

The early recognition of this disease gives promise of its successful treatment, for, if there is one fact which the phthysiologist has demonstrated for curative medicine, it is the curability of phthisis. To-day the words of Brehmer are verified: "*Tuberculosis primis in stadiis semper curabilis.*" The presence of shadows on the screen as determined by the rays is a sign equally as tardy as the recognition of tubercle bacilli in the sputa. We are here concerned only with skiasecopic evidence which betrays the disease at its very incipency even before physical signs are manifest. In this respect the rays are of undoubted importance and we possess a means which permits of the very earliest possible diagnosis. Many of us in our practice meet with the phthisiophobiac and we are now in the possession of means that will often rid that unfortunate individual of his fear. Of course, to depend on the rays alone for purposes of diagnosis would be to invite exclusivism which would be fraught with danger to the catholic foundation on which diagnosis rests. There are two early signs to which I wish to direct your attention, viz., restriction of the excursions of the diaphragm, and the emphysematous x-ray appearance of the lungs. The physiologic diaphragmatic excursions vary according to whether the breathing is quiet or forced. In quiet breathing, the extent of movement is about 1.8 cm. on the right, and 1.5 cm. on the left side; whereas, in forced breathing, the difference in the position of the diaphragm between forced inspiration and expiration, averages 6.7 cm. on the right and 7 cm. on the left side. Individuals with long thoraces show greater excursions of the midriff than deep-chested persons. The restricted diaphragmatic movements must be regarded as a very suspicious sign of phthisis, other things being equal. This sign first referred to by Williams of Boston has received universal confirmation, but, to my knowledge, no theory has been advanced to explain its existence. I have sought elsewhere an explanation for this curious phenomenon and I will briefly summarize my investigations which gave birth to the theory that an emphysematous condition of the lungs exists in phthisis. Rokitsky noted that too voluminous lungs coupled with a small heart characterized the phthysical habitus. No one seemed to have contradicted this observation and as a result it was soon relegated to oblivion. Brehmer revived and vigorously defended this hypothesis. The too voluminous lungs of Rokitsky and Brehmer

are lungs which are practically the lungs of emphysema. In health, the percussion note of the lungs is resonant during inspiration and dull or even flat during expiration. In emphysema, the percussion note is unchanged during the two phases of respiration. This unchanged percussion note heretofore recognized in pulmonary vesicular emphysema is pathognomonic of lungs predisposed to tuberculosis, and in lungs already affected. Associated with the unchanged percussion sound there is an extension of the lung borders manifested by downward lung dislocation and diminution to the extent of obliteration of the cardiac and splenic areas of absolute dullness and diaphragmatic immobilization. As a rule, this lung emphysema in phthisis is limited to the lower lobes and is dependent on the fact that the air entering the respiratory tree travels in the direction of least resistance. Not infrequently, as in the accompanying illustration, the emphysema is associated with atelectatic zones. If the physician were to depend on percussional dullness as an evidence of early phthisis, the affection would never be recognized; lung resonance, not dullness, is the early physical sign of phthisis. The rays are invaluable in the recognition of the emphysematous condition. The lungs seem too large for the chest, the diaphragm is low and its excursions restricted. The lungs appear permanently bright, not alternately so as in their normal condition, and "statuesque" is about the best word to describe their appearance. It is interesting to observe parenthetically, how such lungs contribute to the development of phthisis. Defective pulmonary elasticity means some defect in the pulmonary elastic tissues. It may mean a congenital defect as Cohnheim has observed in a large number of cases of emphysema. A loss of pulmonary elasticity eliminates an important factor, not only in lung nutrition, but in the nutrition of the entire organism.

#### PNEUMONIA.

In this disease the rays are of service in detecting and locating pneumonic areas which resist the conventional physical methods of examination. In differential diagnosis, as for instance in deciding between a pleural effusion and pneumonia, the rays are indispensable. The recognition of the condition of the lungs after apparent recovery from pneumonia is one of the most important but neglected problems of the physician. Here the rays subserve a useful purpose. The sequelæ of unresolved pneumonia are many. I have learned one lesson of which I am proud and that is to observe and treat the lungs after apparent recovery from an attack of pneumonia. Cases of apparently protracted bronchitis in children as well as adults are in reality cases of broncho-pneumonia, the discrete patches of which disease are made evident by the shadows thrown on the screen.

#### EMPHYSEMA.

I have already referred to the appearance of the lungs in this affection. Inasmuch as an emphysematous lung will interfere with topographic percussion of the heart, spleen and liver, the rays offer no obstacle to the correct demarcation of these organs. The co-existence of emphysema with pulmonary tuberculosis not infrequently masks the dullness on percussion elicited in the latter disease, an error which the rays will eliminate.

#### BRONCHITIS.

In this affection I have noted no particular skiascopic changes unless the disease was complicated by broncho-pneumonia, in which instance I have been able to demonstrate shadows limited to the broncho-pneumonic patches.

#### PLEURAL EFFUSIONS.

When these are present, the diaphragm is in slight evidence or is not seen at all. The dark area represented by the fluid casts, as a rule, a more distinct shadow than is observed in most affections of the thorax and the shadow may change on the patient's position being altered. Dislocation of the heart may readily be seen when it exists. In encysted pleurisy, the usual physical signs must yield in a diagnostic sense to the rays. Unsuspected complications of pleurisy, such as tuberculosis and pneumonia, may be determined when the conventional physical signs lead us into error. There is one point which I have noted in pleural effusions, that the heart is dislocated long before there is any displacement downward of the diaphragm. This is in accordance with the fact that the diminished pulmonary suction on the affected side will cause the heart to be drawn over by the greater suction of the opposite side. Now the pressure on the abdominal side of the diaphragm being positive, it is only when the pressure in the pleura becomes more positive that any downward dislocation of the diaphragm occurs. Even in the presence of large effusions on the left side, I have obtained the tympanitic percussion note of the stomach as high up as the sixth rib in the mammary line. In searching for small effusions, the angular spaces on either side situated between the outer portion of the diaphragm and the chest wall should be examined. Pleural thickening, which may often be confounded with small effusions, may be differentiated by a careful study of the angular spaces referred to. Any change in the darkened area, as indicated by changes in the position of the patient, speaks for effusion. If pleural adhesions are present their presence is indicated by limited excursions of the diaphragm.

#### PNEUMOTHORAX.

In this affection the x-ray appearance shows an unusually large area of brightness. The diaphragm lies low and is restricted in its movements. The heart is dislocated toward the opposite side. I lay particular stress on the low position of the diaphragm for it is usual for text-books to teach that the pressure in gaseous effusions into the pleura can not be sufficiently positive to dislocate the diaphragm until the occurrence of liquid effusions.

#### TUMORS OF THE LUNG.

Neoplasms of the lung are indicated by shadows. Their presence may be determined when the usual physical signs are negative. A mere shadow is, of course, only suggestive evidence of a tumor, but the rays enable us to make a diagnosis by exclusion after weighing all the other facts elicited by the skiascopic appearance of the thorax. Enlarged bronchial glands may be detected when all other evidence fails.

The definite localization of an abscess of the lung by means of the rays is an important aid to the surgeon.

#### ASTHMA.

In this affection I have had frequent opportunity of observing a paroxysm while the rays traversed the chest. Often I was able to provoke a paroxysm by packing the nostrils with cotton. The appearance of the lungs is practically that of emphysema with immobilization of the diaphragm. Cessation of the attack is evidenced by mobility of the diaphragm and restoration of the lungs to their natural brightness.

The majority of lung affections, if demonstrable by the rays, throw shadows on the screen. The trained eye

may, by the density of the shadow cast and their situation, determine to a limited degree only, the nature of the anatomic condition. Thus, the presence of fluid in the pleura or a tubercular lung casts more pronounced shadows than a thickened pleura, a lung abscess or a broncho-pneumonic patch. A lung shadow gives one the impression of density and is circumscribed, whereas a thickened pleura yields a less dense and more diffuse shadow. Shadows limited to the center of the lung can not be pleurogenic and this shadow localization is not only of great importance in diagnosis but furnishes an index to the site of the operation in lung surgery, whether the object to be attained be the drainage of a bronchiectatic cavity, opening of an abscess or the location of a foreign body.

Numerous methods have been advocated for focal diagnosis. The simplest aim to determine whether the lesion is located near the front or the back of the chest will depend largely on the general principle, that the nearer the lesion which casts the shadow is to the screen, the less exaggerated and more clearly defined will be the shadow. The respiratory method is available with reference to the chest. The shadow cast in respiration and expiration will not differ materially in position nor in clearness of outline if the lesion is situated near the screen; if, however, it is distant from the screen, the shadows will be greater in extent and their contours will be indistinct. In executing an examination for focal diagnosis, the patient must be examined with the light in front and behind him. Another expeditious method is to mark with a pencil the different points on the anterior, posterior and lateral aspects of the thorax, the location of the shadow; then with a cyrtometer, determine the form of the chest and transfer it to a sheet of paper. Next unite the location of shadow by lines and at the point of intersection of these lines, the lesion may be located (Fig. 4).

I have by no means exhausted in this brief communication all the facts concerning the importance of skiagraphy in pulmonary diseases. Allow me to add that x-ray diagnoses must be based on examination of the entire chest and not of a single organ and the x-rays must only be regarded as an adjunct to other methods of examinations, although no physical examination can be considered as complete without their employment. In conclusion, I have a few brief remarks to make with reference to lung development. I have investigated various prolix methods recommended for such development, employing the methods while the rays were traversing the chest. Many of them have been found faulty; in fact, they produced the original defect which they were designed to correct. I have no time to dwell on these methods at the present time, but simply suggest that the rays be employed after this manner for determining the correctness of a method which has for its object the promotion of inspiration or expiration and further, whether certain methods are of avail in promoting resorption of alveolar or pleural exudates or the relief of lung congestion in valvular cardiac lesions. I am busy at present with a study of these problems, the solution of which are reserved for a later contribution.

**Discovery of Original of Galen's Work.**—The *Vienna Med. Blätter* announces the discovery of the Greek original of Galen's work called the *Sermo Aesculus Empiricost*, hitherto known only in the Latin translation. It was found at Milan by Privatdozent H. Schoene, of Berlin, who has been commissioned to catalogue the medical manuscripts in the libraries of Italy.

## AN ANALYSIS OF FIFTY-TWO CASES OF TETANUS FOLLOWING VACCINIA.

WITH REFERENCE TO THE SOURCE OF INFECTION.

1839-1902.\*

ROBERT N. WILLSON, M.D.  
PHILADELPHIA.

The following analysis of a large number of instances of tetanus in the course of or following vaccinia, was prompted by the occurrence of a case in the practice of the writer, and by its fatal termination in spite of an early diagnosis and heroic treatment. During the five months that have succeeded the report of this case before the Philadelphia County Medical Society an attempt has been made to ascertain the details of such a number of similar cases, both in recent and past years, as would warrant a conclusion as to the source of the tetanus infection.

The proportions of this task can be realized only in part even by those who have engaged in similar work. There is abundant indication that tetanus has occasionally appeared in the course of and following vaccinia from the time of Jenner down to the present day, and it will be noted that the cases included in this paper date back as far as 1839. Many such cases, however, have for one reason or another only rarely reached the attention of the profession. While some physicians have desired the truth at any cost, others, through an unwise zeal for the protection of vaccination from discredit, have joined with many firms that manufacture vaccine to suppress and discourage reports of this unfortunate complication of a most beneficent measure. One well-known medical representative of a vaccine firm ventured in an attempt to dissuade the writer from his task on the ground that he (the writer) would incur the risk of an unwilling and unjustified association of his name with a particular commercial interest. Perhaps, therefore, in the beginning of such an analysis as is proposed, and with a view to clearing his person of any such possibility, real or imagined, it may be well for him to state in unqualified terms that he not only is not connected in any way, personal or financial, with a commercial interest of any description, but that he has at no time contemplated such a business connection. While in certain cases these obstacles have resulted in a less complete and systematic marshalling of the facts necessary to prove one or other possible source to be the real origin of the tetanus infection, the clinical histories and statistics cited below are in the main fairly comprehensive and full, and offer an opportunity to everyone for unbiased study and self-conviction. The object of this analysis is to prove:

1. The source of the tetanus infection: whether the virus, or some other medium.
2. The time of infection: whether synchronous with the vaccination, or subsequent to it.
3. If a secondary infection (not carried by the virus); then due to what circumstances, and preventable by what means.

Brief histories of fifty cases occurring between the years 1839 and the present time are submitted, withholding in all cases the name of the physician, and usually at his own request based upon obvious and honorable reasons. A number of other cases have been found in the newspaper literature and through correspondence, but with such meager data and indefinite facts as to render them unsuitable for use in such a connection.

\* Read at a meeting of the Philadelphia County Medical Society, April 23, 1902.

CASE 1.—Seen for the first time on July 31, 1839. Isabella, negroess slave, on Orange Grove Plantation. Date of vaccination not given. Suppurating ulcer at site of vaccination. Difficulty of deglutition, rigidity of muscles of face, and sensation of stricture at top of sternum. Rigidity of all extensor muscles of the extremities. Two days later twitching of the extremities, rigidity of the jaws, inability to protrude the tongue, arm sore from cauterization with  $\text{AgNO}_3$  and a lye poultice. Eschar the size of a dollar. . . . Two weeks from commencement of attack twitching of muscles has almost entirely ceased. Patient opens mouth easily. August 25, at work and well. Treatment: Cups to spine, enemata of lobelia and opium (5*℥* of solid opium, and 2 lbs. of laudanum in the enemata) during the course of the tetanus.

CASE 2.—Seen at Lowell, Mass., in October, 1845. One of two children, vaccinated by the mother from a child's arm with a darning needle. The child from whom the virus was taken was perfectly healthy, though the mother noticed that the lymph was thick and yellow. Case 2 was 5 years old. In a few hours it became sick, nervous and prostrated. Convulsions set in, and the child died in about 24 hours after the vaccination. At the site of vaccination there was a dry and angry-looking wound, without an areola, and apparently extending through the true skin.

CASE 3.—Aged 7 years. Vaccinated by mother at same time with preceding case, and in same manner. This child also suffered from severe nervous symptoms and prostration, also from convulsions, but ultimately recovered. A dry angry ulcer was also to be seen at the site of this vaccination. Gradual recovery presumably lasted over months. The coincident occurrence of two infections, one violent and fatal, the other severe but prolonged and ending in a tedious convalescence, and the fact that both cases were marked by the presence of an angry vaccine ulcer, as well as by convulsions evidently due to infection through the wound; all these circumstances point to the strong probability of a tetanus infection in Cases 1 and 2, though trismus is not mentioned and evidently was not observed.

CASE 4.—Edw. K., 3½ years old. 'Never ill since early infancy. Vaccinated on or about May 15, 1879, by German midwife, with virus inserted at two points on the left arm. At one of these sites is a normal-looking almost dry crust, and at the other a highly inflamed ulcer from which the "crust had evidently been torn." Seen June 5 and found suffering with tetanus, from which he died before 8 a. m. the following morning. During the day he exhibited a peculiar expression of face, and an occasional elevation of his shoulders and arms culminating in a pronounced convulsion in which he fell from his chair to the floor. Two other spasms quickly followed. Sardonic grin pronounced and trismus extreme; several convulsions during the physician's visit. These recurred with increasing severity until death supervened.

CASE 5.—J. McL., aged 9, healthy personal and family history. Vaccinated Jan. 6, 1882, in Auburn, N. Y., with "bovine quill" virus, "other lymph from the same source had been extensively used with generally satisfactory results by the vaccinating physician." January 26, on going to bed, complained of stiff neck. Next morning he could not open jaws. During night had chills, and during day following pain at pit of stomach, shooting to the back and thence to the whole body, and accompanied by tonic spasms. When seen marked opisthotonos was present. On touching him "shooting spasms" pervaded all the contracted muscles, including the facial. Pulse 90, temperature 98.5 F.; mind clear. Vaccinated arm showed a large irregularly-shaped ulcer, one half covered with dark incrustations, edges excavated, large dingy granulations, bits of pus adherent. Arm swollen, with erythematous inflammation. Axillary glands enlarged and tender. No other lesion on the body. Had used a privy in an attached but unwarmed building, had "taken cold," and the symptoms of tetanus promptly developed. Death on 10th day from commencement of the tetanus. Lower limbs became somewhat involved in the tetanoid contractions, the upper not at all. Large doses of morphia were used. The physician states that there were many other severe ulcers from the use of the virus, but no other cases of tetanus.

CASE 6.—D. M., aged 40. Tall, healthy man. Vaccinated in Maryland, about the middle of January, 1882. Some days later exposed to cold. Arm soon became much swollen and the skin around the vaccine wound much inflamed. On February 8, when seen, exhibited a large deep ulcer, size of a silver dollar, and no other lesion was found on the body after a careful search. For several days had slight bronchitis and vague fugitive pains in the back. February 7, first noticed slight stiffness of jaw muscles. On the 8th could only separate teeth to a slight degree. Reflexes exaggerated, slight photophobia; considerable hyperesthesia. Pain from irritated region if skin is brushed. Body bathed in perspiration. Muscular spasms in lower extremities. February 9, convulsions were excited by breath of air or movements of patient's body. Marked trismus. Temperature 100.4 F., resp. 28, pulse 110. From this time on opisthotonos well marked. Coma on February 12; temperature 102 F., resp. 36, pulse 140. Up to death on February 13, slightest irritation produced convulsions. Constipation persistent. Treatment, chloral and potassium bromid in large doses.

CASE 7.—B. J., mulatto boy, aged 5. Vaccinated at Columbia, S. C., Feb. 9, 1882, on the left arm, and at the insertion of the deltoid. The virus was carefully selected humanized lymph. On March 8, one month later, he had pain in the stomach and inability to open mouth. When sitting his body and neck were bent backwards, the muscles of the back, chest, the masseters, internal pterygoids, were in a state of partial rigidity. There was incomplete trismus and some embarrassment of respiration. The ulcer was healthy-looking and painless. On March 10 the ulcer was "bathed in healthy pus," and the tetanus more pronounced. Trismus was marked and the muscles of the lower extremities involved paroxysmally. The boy lived 15 days, when death ensued. Treatment, potassium bromid, physostigma and chloral.

CASE 8.—Carlos C., white, aged 2, was vaccinated in the month of April in Cuba. The vaccination was successful and ran a normal course. Inflammation then commenced at the site of the vaccination pustule, converting the latter into an ulcer, which, when first seen, had burrowed deep into the tissues. There were typical symptoms of tetanus. No other lesion was to be found on the surface of the child's body. Large doses of chloral and laudanum were employed, but in spite of active treatment the child died on the fourth day.

CASE 9.—G. E. B. (from Report of Royal English Commission), was vaccinated by the public vaccinator by the arm to arm method,

from a child whose vaccination ran a normal course. Six others were vaccinated from the same child, all running a normal course. On 8th day the vaccination appeared normal. No dressing is mentioned as having been used up to this time. On the 9th day redness appeared, extending about an inch around the vesicles. Later a bluish appearance, purulent discharge, and the arm was bathed with oatmeal water, dressed with zinc ointment on red rags, and a shield superimposed. The discharge was thick and offensive. On October 1 the mother poulticed the arm. Next day the mouth was "drawn tight." Marked tetanic symptoms followed, paroxysms of opisthotonos, in one of which the child died on October 5. Poultry and tame rabbits were kept in the yard, close to the door; and at a house one-half mile distant an infant, 10 days old, died about the same time from umbilical tetanus.

CASE 10.—Dionisio G., negro, male, aged 9 months, was vaccinated in Cuba at a municipal dispensary, on July 12, 1891. He was found in a cot covered by a dirty quilt, and the room and the walls and floor were covered with dirt. On the 16th the vaccination was successful. On the 18th, 19th and 20th he had a little fever, which soon entirely disappeared. During this time he continually crawled around the room and the yard on his hands and knees as usual. On the 31st of July he had a sudden convulsion, lasting but a short time; on August 1, another, at which time trismus was present. The characteristic and classic symptoms of tetanus rapidly asserted themselves, and the child died in 32 hours from the beginning of the attack.

CASE 11.—M. D. W., was vaccinated on Nov. 6, 1893; a white child, female, aged 5½ years. Strumous diathesis, with suppurating cervical adenitis. Child neurotic, of weak vitality, slight ailments always affecting her profoundly. Vaccinated with fresh ivory point of bovine virus, using alcohol and clean towel in preparation of the field of operation. The latter was covered with Lister's green protective and bandaged. On November 24, 18 days later, the wound was "not doing well." Vaseline had been taken from a partly used bottle, into which those who used it had dipped their fingers, and a quantity had been set aside in the closet for the purpose of dressing the wound. When first seen the child was indisposed, temperature 100.5 F. The ulcer on the arm was the size of a half dollar, deep, and contained a quantity of sanious pus of a very feld odor. The child had been at play every day since vaccination, and had at no time suffered any inconvenience. Child now became depressed, thirsty, apprehensive, and had slight strangling attacks. On December 2 some rigidity of the cervical muscles and pains in the back. Constipated, with suppression of urine. Arm appeared healthy at this time, temperature and pulse normal. Aphthous stomatitis and several badly decayed teeth present. At midnight a convulsion, opisthotonos, apnea. Marked trismus of risus sardonius. On December 4, typical convulsions. On December 5 rales at base of left lung posteriorly, and later in the right lung also. Six more slight convulsions and death followed. It was learned that the father had taken the child for a walk on November 30, and in the stiff breeze she complained of sharp pain in the "right throat," posteriorly to the angle of the jaw. She had at this time aphthous stomatitis, with ulcerative lesions on the lips and tongue.

CASE 12.—A. P., school-girl, white, and 7 years of age. Was vaccinated on Oct. 2, 1896, in Philadelphia, by one of the official vaccine physicians, who used upon this as well as the following case, "fluid vaccine" from Milwaukee. This vaccine was at a later time diluted with glycerine, but, according to the physician, this was not true up to the time of vaccination of these cases. No other cases of tetanus developed from its use to his knowledge. When first seen the site of vaccination showed a cup-shaped ulcer ¼ inch deep, ¾ inch wide, and 1 inch long, discharging pus, and the immediate vicinity slightly swollen and indurated. Trismus marked, temperature 100.5 F., pulse 120, resp. 20. On October 10 risus sardonius also marked, and three slight convulsions. On the 11th opisthotonos extreme, temperature 101.2 F., pulse 120, resp. 36. From then until the 15th the same condition, with profuse sweating. Opisthotonos relaxed at this time, but returned upon the slightest disturbance. Muscles of abdomen, chest, and all of the extremities in marked contraction, and continually bathed in cold perspiration. Perfect control of urine and feces and was fed by means of small rubber catheter, and for a few days by nutrient enemata. On the 17th patient was able to open mouth ¼ inch, tongue very swollen and coated and a terrible stench coming from the mouth. Trismus gradually relaxing. On the 26th, tongue much swollen and covered with mucous white ulcers about the size of a dime. Gums swollen and spongy; slight bleeding. On November 2 there had been a pustular eruption on the face, neck and buttocks for two days, which now spread to the arms and thigh, and was quite painful. Several crops appeared in the next two weeks. By December 1 the child was perfectly well. The treatment was local antisepsis, together with the use of chloral and bromids. On October 10 two coverslip spreads from the wound showed large numbers of staphylococci and streptococci. No cultures were made.

CASE 13.—E. S., white, male, aged 8. Vaccinated October 3, by the same physician, and with the same fluid vaccine. Until then perfectly well. When seen on Oct. 23, 1896, the boy was slightly feverish (101 F.), resisted inspection of the throat, which was persisted in, however, and a whitish, more or less necrotic appearance noted. The tonsils and uvula were swollen. The masseter muscles were contracted and there was present the risus sardonius, when he tried to contract the muscles of expression. The reflexes were active, the muscles of the neck and the back stiff. A culture was taken from the throat and a mixed growth of diphtheria bacilli found, of virulent type, causing characteristic postmortem appearances in guinea-pigs. The child's arm about ten days after vaccination had become ulcerated in appearance and had grown steadily worse since that time. When seen was necrotic, a depressed ulcer being present with some purulent secretion. Antitoxin was administered on the next day. Frequent convulsions had occurred during the night, sleep intervening. Temperature 100.4 F. Condition on the following day the same. Trismus extreme. Mouth foul. This condition continued until October 30, when he became more relaxed, and on October 31 he could open his mouth slightly and take a little food. Recovery was slow, but eventually complete.

CASE 14.—A. K., private in 3rd Nebraska Regiment, 1st Division, 7th Army Corps, U. S. A. Died at Havana, Cuba, in 1899, "from tetanus resulting from infection from vaccination." No details of the clinical history obtainable, and evidently no record preserved.

CASE 15.—C. R., colored soldier, private, Company A, 24th Regiment, U. S. L. Vaccinated July 17 with glycerinated virus. Careful asepsis at time of operation. August 3 reported at sick-call, complaining of pain in his neck and stomach. Had been sick all night. Diagnosis of tetanus made on August 4, when trismus was marked. Convulsions appeared, increasing in frequency until they occurred every two minutes at 11:30 a. m. Temperature at 1 p. m. 99.6 F. Could not swallow. Retention of urine. Ineffectual attempt at passing catheter over two strictures. Hot water bags produced voluntary micturition later. Convulsions and opisthotonos almost continuous until death occurred at 1:30 a. m., on August 5. The vaccine wound presented throughout an ulcer half the size of a half dollar, with no surrounding swelling or infection of the tissues. The patient was conscious at all times, and complained of great pain in the neck and abdomen. Temperature at time of death 107.4 F., and one-half hour later 108.5 F. The treatment consisted of large doses of chloral and morphia.

CASE 16.—Female, aged 10, white, was vaccinated in Brewster, New York, about Oct. 1, 1899, aseptically and with glycerinated lymph. The reaction was severe, with much pain and swelling from the fourth day after the operation. Three days before the development of the tetanus these symptoms had greatly increased. The physician states that there were three sources of infection other than the vaccination, of which the most probable was the application of fish lard exactly 18 days after the vaccination, and synchronous with the exaggeration of the inflammation. The case ran a typical course of tetanus and terminated fatally.

CASE 17.—Native Porto Rican child, male, was vaccinated by the American authorities during 1899, in San Juan. The tetanus appeared a number of days after the child was vaccinated. The virus was on a dried point, and had been produced at a vaccination station established by the military government of the island. "The case received thorough investigation, with the conclusion that the vaccination primarily had nothing to do with the secondary disease." Unfortunately the records of this case were lost, but Lieut.-Col. Van R. Hoff writes in a personal communication: "Among the details that had to be considered was the question of secondary infections which are very apt to occur in tropical countries, especially tetanus, which you will observe by looking at the records of the Superior Board of Health is the cause of considerable mortality in Porto Rico. It was determined to investigate every case reported. The one referred to . . . was the only case brought to our attention . . . As to source of infection, the lower classes in Porto Rico are no more cleanly than elsewhere, and very little care was taken by them to keep the parts clean. Asepsis was followed in the operation, but it is not believed that it was maintained and secondary infection might have occurred in many ways. The patient died." About a million vaccinations were executed during the period referred to (1899-1900) by the American military authorities in Porto Rico. In investigating the question of possible cases in the records of the War and Navy Departments the following reply was received to an inquiry on the subject, from Surgeon-General Rixey, of the U. S. Navy: "During the last five calendar years there have been three cases of tetanus in the naval service, and one death from that cause. None of these cases was associated with vaccination. In accordance with U. S. Navy Regulations, each person is vaccinated immediately on enlistment. During the last five years there have been 63,465 persons enlisted in the Navy and Marine Corps. . . . During the last five fiscal years there have been distributed from this bureau 70,253 vaccine points. Additional virus has been obtained from time to time, in emergencies, by cruising ships on foreign stations."

The cases cited in this series include the few cases recorded in the files of the War Department, of tetanus following vaccinia.

CASE 18.—M. E. A., female, aged 8, was vaccinated about Nov. 27, 1900, with ivory points, in Paris, Tenn. At the same time several other members of the family were vaccinated, and all had very sore arms. There was no other case of tetanus in the family. The scab was knocked off from the child's arm by a schoolmate, and the mother dressed the sore "with some wadding removed from an old quilt, and this cotton was allowed to remain on the arm until the tetanus was discovered (10 days)," about three weeks after the vaccination. Tetanus antitoxin was ordered from Memphis, but never used. The case died.

CASE 19.—Male, white, aged 8, was vaccinated Jan. 3, 1901, with glycerinated lymph at Kalamazoo, Mich. Aseptic precautions used at time of operation, and shield used until the arm was dry, when it was removed and the mother instructed to keep the clothing clean and use no dressing. The vaccinia was normal until the 14th day, when the scab was torn off at school. The ulcer was filled with watery granulations, and there was considerable watery discharge. Mother now instructed as to aseptic dressing, but the instructions were not carried out. On January 27 tetanus developed. The arm was found in a filthy condition, also the shirt-sleeve over it. There was no dressing over the ulcer, which was filled with unhealthy granulations. Symptoms of tetanus were classic. Slight improvement followed the use of antitoxin. Morphin and chloroform also used. The boy died on January 31, five days after the first symptoms of tetanus. Twenty-four days had elapsed from the date of vaccination to the development of tetanus, and ten days previous the scab had been torn from the wound.

CASE 20.—Female, aged 21, was vaccinated unsuccessfully. Re-vaccinated on the leg on March 8, 1901, with calf's lymph supplied by the Health Board of the City of Glasgow, Scotland. The limb was carefully cleansed and after the operation a "large adhesive thick felt or bunion plaster was then applied around the vaccination mark, and was kept in position by a strip of adhesive plaster." The vaccination was successful, though the symptoms were quite insignificant. On the 18th she experienced a severe draught, complaining at the time. On the 20th pain in the back and stiffness in the neck and jaws. No sore throat. Adhesive plaster had never been removed since the first application (13 days), and when crust and plaster were removed the ulcer did not look particularly healthy. Covered by a grayish-colored slough and a discharge of thin, dirty yellow pus. Bread poultice used, and on the 21st day the wound healed completely. March 22 the jaws became stiffer, ill by evening the patient could only open them with difficulty. Head distinctly retracted, much rigidity of the muscles of the neck, and some of muscles of the abdomen. Hysteria considered, but no stigmata found. Temperature normal, pulse 68, and regular. Varying improvement and retrograde until the 24th.

Feet then so strongly flexed as to continue the line of the legs. Consultation with Sir Hector Cameron and Prof. T. K. Munro, and diagnosis of tetanus made. Until end of April intermittent fever and gradual improvement. April 6-22, spasms of muscles upon any sudden movement. Could not chew owing to rigidity of jaws. Sat up in bed by the end of the first week in May. Trismus was the last symptom to disappear. The arms were never involved. Perfectly well by the end of June. Treatment by means of large doses of chloral. This was the only patient of a large number vaccinated on the same day to develop tetanus.

CASE 21.—Mary E. R., white, aged 12, was vaccinated for the first time in her life in Burlington, Vt., with dry points. Tetanus developed on Oct. 21 (vaccinated Oct. 2), 1901, and several days prior to its appearance the girl had assisted in taking up and potting plants from the garden, although with a large angry ulcer at the site of vaccination. Dr. B. H. Stone, bacteriologist of the State Laboratory of Hygiene, cultured six samples of earth, taken from various streets, alleys, and gardens of the city. From all, and from the garden earth at the residence of this case, pure cultures of the tetanus bacillus were obtained, "which killed white mice in several hours. The animals developed typical tetanic spasms."

CASE 22.—Female, also aged 12 years, and never vaccinated before. Vaccinated on the arm with dry points in Burlington, Vt., in October, 1901. Twenty-one days later tetanus developed. This girl also had a large ulcer at the site of vaccination, and neither she nor the preceding case "had the vaccination wound protected until some time after a scab, which had formed, had been removed, accidentally or otherwise, and then the dressing was done at home." These were the only cases among over 8000 vaccinations in the town with the same virus. The culture experiments noted in the last case were made in reference also to this.

CASE 23.—F. I. K., white, female, aged 11 months. Vaccinated at Rosemont, Pa., 28 days before she was seen by the writer. A sister was vaccinated at the same time and had a severe ulcer, but tetanus did not develop. The father is a coachman, and the family lived over a stable. When first seen the wound was angry and foul smelling. The inflamed area corresponds closely to that covered by the shield, which had not been removed since the vaccination. No dressing had been worn over the perforated shield. Symptoms rapidly increased, in spite of large doses of carbolic acid, used hypodermically, and antitoxin administered within the first 24 hours and repeatedly after. Chloral and bromids were also used in full doses. Trismus was marked, opisthotonos almost continuous and the child died in a convulsion 36 hours after the beginning of the attack. The wound, which was thoroughly curetted, was full of indurated tissue and covered by a mass of coagulated pus and lymph. Cultures gave a profuse growth of staphylococcus albus on all the media. No growth of the anaerobic bacteria could be obtained. (This case has been reported in full at a previous date.)

CASE 24.—W. J. B., male, white, aged 7, vaccinated in Camden, N. J., on Oct. 12, 1901, with glycerinated virus, marked good until Dec. 26, 1901. Aseptic care was used in the operation. About November 1 the scab was lost off while at play, and, according to his playmates, he picked it up from the ground, replaced it in the wound, and bandaged or tied it in place. Tetanus developed on November 1. Trismus and opisthotonos were present; the case grew rapidly worse and died Nov. 3, 1901. The boy's brother was vaccinated with the other half of the virus from the same tube, and at the same time. His vaccination was successful, and ran a usual course free from tetanus.

CASE 25.—L. E. C., female, white, aged 16, vaccinated in Camden, N. J., on Oct. 14, 1901, with dry points, marked good until Dec. 10, 1901. Asepsis was observed in the operation. A shield was worn and allowed to remain in place until it became glued fast to the surface with the excessive discharge. There was an open sore, large and irregular in shape. Trismus appeared on Nov. 8, 1901, and at first the tetanus seemed to run a mild course. After a short time the symptoms increased in severity and the patient died with opisthotonos and convulsions on Nov. 15, 1901.

CASE 26.—E. S., female, aged 6, vaccinated with glycerinated points on Oct. 19, 1901, at Rosemont, Pa. Aseptic care used during the operation. A shield was applied perforated in the surface to admit the air. The father was a stableman, and the house adjoined the stable. The child had been playing continually in the garden, and had been seen with a playmate shortly before, both "throwing earth at one another." Tetanus appeared on Nov. 10, 1901, and convulsions began the next evening. The next day well-marked stiffness in the jaws and back of the neck. Symptoms all increased, with locked jaw and opisthotonos, and death from exhaustion on November 19. The vaccination wound was clean, granulating and healthy, during the nine days of illness, and during the same time there were present two decayed and bleeding teeth and a stomatitis that was almost gangrenous, that had been neglected. The treatment consisted of the usual depressor-motors and no antitoxin. The same physician had attended ten cases of tetanus (no others in the course of vaccinia), of which four were treated with antitoxin, two recovering and two resulting in death. Of the remaining six (treated without antitoxin) only the case under discussion failed to recover.

CASE 27.—A. M. W., white, female, aged 11, healthy and of large build, was vaccinated on Oct. 19, 1901, with glycerinated tube lymph, marked good until Dec. 10, 1901. Residence, Camden, N. J. Aseptic care employed in the operative procedure and a paper-mache shield superimposed and left in place until October 26. The wound then looked healthy, the vaccination appearing normally successful. She was next seen by the physician on November 6 (17 days after vaccination), when she appeared very nervous and excited. She had headache, and back and limbs were sore, with sharp lancinating pains in the neck, masseter muscles and the larynx. On attempting to eat a piece of candy shortly before she had a spasm of the facial muscles. The vaccination wound was purplish red, soft and boggy, and had a hard core in its center. A thick sanguinous discharge was oozing from the ulcer. The core was removed and found to be about a half inch in depth. The shield had been discarded seven days before and a coarse rag tied on the arm. November 8 frequent localized convulsions, and later of whole body. During the evening of this day coma set in. Many severe convulsions and almost continuous opisthotonos through the night. Complete loss of control over the bowels and urine. Death

on November 9 in terrible agony. Treatment, potassium bromid, chloral and morphia.

CASE 28.—J. G., male, white, aged 11, was vaccinated in Bristol, Pa., on Oct. 19, 1901, with tube virus. Aseptic care of the operative surface, but no care taken with the wound subsequently. Playmates state that patient, while refereeing a game of basketball on November 9, took the bandage from his arm and threw it on the ground, afterwards replacing it upon the arm. The ulcer had been very severe from the beginning, but when seen on November 10 in Philadelphia, where he was taken for treatment, it was badly infected. Tetanus had appeared 24 hours previous. The actual cautery was applied and formalin injections used, and on the following day intracerebral injections of antitoxin were resorted to. There was marked and almost continuous opisthotonos and severe convulsions followed the slightest disturbance. Death took place on November 11, about 28 hours after admission to the hospital.

CASE 29.—B. R., female, white, aged 7, was vaccinated in Camden, N. J., about Oct. 1, 1901, with dry points, and upon the left arm. Her sister, also a child and two other children, were vaccinated at the same time and with the same virus. All four had severe and deep ulcerative processes, one requiring six weeks before it healed, another about nine weeks, and a third not having completely healed at the time of writing this record (over five and one-half months). The patient's arm was equally inflamed. A shield was applied over the wound and retained in place for three weeks. The arm was then so swollen and inflamed that the shield was removed, a deep ulcer being present, discharging fetid pus. At this time an attempt was made to care for the wound aseptically, with a boric acid wash, and an ointment applied. At one time a flaxseed poultice was applied, and over the wound linen rags were placed after boiling. Instead of healing the ulcer burrowed deeper, and seven weeks after vaccination the mother noticed at dinner time that the child's mouth would not open properly for the reception of food (Saturday). On the same afternoon, however, the patient walked to the center of Camden (two miles) to have her picture taken. She slept poorly through the night and next morning could not walk straight. Stood "like an old woman" as she herself said. On the following day, while lying on the sofa her back suddenly arched and she had a severe convulsion. At this time the jaws were tightly locked and the muscles of the back and neck were rigid, as also those of the abdomen. Opisthotonos was not constant, but increased in frequency throughout the week, with occasional convulsions until Saturday (the 8th day) when she died. The mind was clear during the entire period, and just before the final convulsion she talked with her mother. She was fed throughout by enemata. Antitoxin was not used. During the time from the vaccination to the development of tetanus there was neither an abrasion of the skin at any other point on the body than the vaccine sore, nor even a decayed tooth. The child had always been healthy and well since infancy, when she suffered from malnutrition. Her mother attended the child during the time of her illness and gave the above intelligent and clear statement. The physician refused all information on the subject, so that the treatment could not be learned. Case 35 occurred within a few streets of the home of this case.

CASE 30.—A. B. C., white, female, aged 8, was vaccinated in Camden on Oct. 21, 1901, with glycerinated tube lymph. A paper-mache shield was used continuously until the 28th, when a fresh shield of a different pattern was applied. The vaccination then appeared healthy. During the evening of November 11 she called at my office and complained of headache, feverishness, etc. Did not sleep well during the night. Next morning was nervous, had pain all over body, and especially in the muscles of the back of the neck. Next morning there were trismus, opisthotonos, and convulsions rapidly increased in severity until 7 p. m. She then became unable to swallow and was fed by enemata. She died in a convulsion shortly before 3 a. m., on November 14. The treatment employed was counter-irritation along the spine, morphia, and four injections of antitoxin (each 500,000 units). Nitrite of amyl was also used. Her schoolmates state that the patient frequently fingered the wound, and exhibited it to them.

CASE 31.—W. B., white, male, aged 16, was vaccinated in Camden, N. J., on Oct. 14, 1901, with glycerinated virus, marked good until Dec. 26, 1901. Asepsis was employed in the operation. A shield was applied and had not been removed nor the arm cleaned until he complained of stiff neck on Nov. 4, 1901. This shield was a simple bunion plaster. When seen the arm was swollen, and the wound was dry and black, emitting a bad odor. The wound was curetted and dressed. Opium and the depressomotors were used, and later antitoxin. The physician who vaccinated the patient stated that the latter was not well when the operation was done. He also denies that the case was one of tetanus. According to the attending physician, who reported the case, the symptoms were unmistakable, including trismus, convulsions, incontinence of urine, and subsequently marked paralysis of the limbs. After four days the trismus relaxed and convalescence was steady from that time.

CASE 32.—E. H., male, white, aged 11, was vaccinated in Camden, N. J., on Oct. 23, 1901, with glycerinated points. Asepsis had been used over the wound, and when seen on November 13 there was a large ulcer on his arm, the size of a half dollar, and in this was matted the sleeve of a new merino gray shirt that had never been washed. The shirt had been worn since the 13th, and no care had been taken of the wound. On November 11 the boy said to his father that his jaws seemed stiff. He slept all night, but in the morning felt stiff all over. His mother carried him down to breakfast. About one hour later she noticed that his head was drawn back, though he could talk plainly. He was seen by the physician about 10 a. m., on November 12, at which time trismus was so marked that he could barely get his tongue between his teeth, and could not talk. Convulsion soon set in, with marked opisthotonos, and the boy died at 4:30 a. m., November 13. Treatment, chloral and bromids. Rectal feeding.

CASE 33.—F. C., white, male, aged 5, was vaccinated in Camden, N. J., on Oct. 25, 1901, with glycerinated tube virus. Aseptic cleansing of the arm was carried out. For a greater part of the time no dressing had been worn upon the wound. About a week before the development of tetanus the boy had ridden on an ice wagon and had torn his arm upon the ice hook. Neither this wound nor the vaccine ulcer was attended to properly. The case was first seen by the physician on the evening of November 8,

when he complained of a stiffness in his cheek muscles. He was seen again at 5 a. m., next morning, when the symptoms of tetanus were distinct. The case was unusually severe with opisthotonos and convulsions from the start, and died at 3 p. m., of the same day. The boy's home was within a few feet of a stable, not very clean, where he played much of the time. His brother, three years his junior, was vaccinated at the same time, and with the same virus; the vaccination was successful and gave no bad results.

CASE 34.—M. W., white, female, aged 8, was vaccinated in Camden, N. J., on Oct. 26, 1901, with glycerinated tube virus, marked good until Jan. 5, 1902. Asepsis had been employed in the operation. The vaccination had taken, but never was severe and when called to see the case the physician found the vaccine wound entirely negative. This was on November 15, at which time tetanus was well marked by trismus, rigidity of the muscles of the neck and jaws, as well as of the abdomen. The case ran a mild course, however, and has since slowly recovered. No information can be obtained as to the treatment.

CASE 35.—G. O., colored, female, aged 9, was vaccinated in Camden, N. J., on Oct. 26, 1901, with dry points (statement also made in another report of Camden Health Board that the virus was in the form of glycerinated points), and asepsis was observed in the procedure. The vaccination was done at the City Dispensary. No dressing was worn over the wound for most of the time. The vaccine wound was a severe one, but when seen by the physician it had a healthy appearance, though still open and discharging a mucopurulent material. There was also an open sore on the inside and corner of the lower lip. The case at first ran a mild course, though there was marked trismus and rigidity of the neck and facial muscles. Depressomotors were used and the case seemed to respond to treatment until November 26, when active convulsions appeared and the child died during the course of the morning. The patient's brother was vaccinated at the same time and with the same virus and had no bad results, though the vaccination was successful. Case 29 occurred within a few streets of the above.

CASE 36.—F. H., white, female, aged 4, was vaccinated in Philadelphia, on October 26. A tube of glycerinated virus was equally divided between the arm of the patient and that of an older sister. The latter had been successfully vaccinated four years previous and the revaccination was of no effect. The patient was healthy at the time of vaccination. Her home is a brick house without a cellar, and connected with a stable by a single door. Both the stable and the house are untidily kept. In 5 or 6 days a typical vesicle formed and the vaccination ran a normal course. On November 13 (18 days), when seen, the wound was not scabbed over: was angry looking; and there was a small surrounding zone of inflammation. Patient complained of pain in the thigh, muscular rigidity in the neck, back and thigh, and great fear that she might get her tongue between the teeth and bite it off. Opisthotonos was pronounced over portions of two weeks, the muscular rigidity and contractures remaining much longer. Recovery was not complete until some time during the latter part of December, when she was active and well. The treatment included the use of local measures, as well as bromids and opium. No antitoxin was used. This was the only case among a large number of vaccinations to develop tetanus.

CASE 37.—H. P., white, male, aged 7, was vaccinated in October, 1901, at the Atlantic City Hospital, N. J., with glycerinated virus. A shield was applied and worn three days. A rag was tied around the arm. The child played constantly in an adjacent yard where a house-mover kept his lumber, some of which was in a bad state of decay. When seen the vaccine sore was not particularly in evidence, the pain and soreness being entirely confined to the lumbar region. On the second visit the stiffness of the jaws and neck were marked. He was then removed to the hospital (22 days after vaccination). Opisthotonos grew very marked with repeated convulsions, until the child died on the third day after admission. The treatment consisted of antitoxin injections, chloral and bromids.

CASE 38.—A. T., Jr., white, male, aged 12, was vaccinated in Bristol, Pa., on Nov. 3, 1901, with glycerinated tube lymph. A shield was placed over the scarification, but allowed to remain for days until it finally became filled with the discharges from the sore. The shield was finally removed and a fresh one applied. With the shield came away a large quantity of pus and also the scab. The next day the jaws were set (November 24). At this time there was a deep ulcer at the site of vaccination. The tetanus was severe, with opisthotonos; muscular rigidity that was quite general, and convulsions. Trismus lasted without intermission until death on November 27. There were no other lesions on the boy's body at any time after vaccination up to the time of death. Cannabiz indica was used in large doses, but with no benefit. No antitoxin was used.

CASE 39.—J. T., white, male, aged 10, was vaccinated Nov. 4, 1901, with glycerinated points in Bridgeton, N. J. No dressing was used and on November 22 the scab came off, the dressing from this time on being a rag. His playmates state that prior to the loss of the scab it had been his habit to pound the arm violently with his fist, apparently to show them that it did not hurt. It was also his habit to finger the wound and exhibit it to his playmates. He had at first worn a shield, which had not been entirely removed nor the arm cleansed until the scab came away (22 days). Directly in the rear of his house is a stable, about 40 feet away, where there is a horse kept by the father of the boy, and where the latter sometimes played. Tetanus first appeared on November 27 (23 days after vaccination). Trismus on the next day was well marked and the general appearance of the boy was one of distress and anxiety. At first the case seemed of the subacute type. The closure of the jaws was never complete, and the patient was able to take food until 24 hours before death. On the day before death there was a sudden exaggeration of all the symptoms, and in the frequency and length of the convulsions. Death occurred from exhaustion on the evening of November 30, about 5 days after the onset of the initial symptoms. The treatment comprised carbolic acid injections, and large doses of chloral and bromids. No antitoxin was used. This was the first death from four or five thousand vaccinations in the city.

CASE 40.—A. H., white, female, aged 13, was vaccinated in Camden, N. J., about November 4, by a sergeant of police (also said to have been by a druggist). Form of virus not known. Trismus, and rigidity of neck and body were very marked. There was an ulcer at the site of vaccination about the size of a quarter-dollar-piece, with a thin layer of pus on the surface. Induration  $\frac{1}{2}$  inch in all direc-

tions. Tetanus developed on November 25, trismus being marked and the contractures and spasms violent from the beginning. The child died on the following day (November 26) in a convulsion. The child had been washing dishes a few days after the vaccination with her sleeves rolled up, had then played with the dogs (kept in the house) on the floor, and then dressed her wound (herself), as usual, with a rag. This was not an unusual performance. The entire indurated area, with the ulcer, was excised, the parts disinfected as far as possible, and the patient injected with 5,000,000 units of antitoxin above the wound and in the back. Bromids and chloral were also given, but with no effect, death taking place in 36 hours.

CASE 41.—Mrs. A. D., white, aged 24, was vaccinated in Philadelphia about Dec. 9, 1901, with glycerinated tube lymph. Her arm became very sore and a crust formed at the site of the vaccination. The physician did not clean the arm, and heated his scarifying needle over a common lamp, according to the story of the patient. No dressing was applied over the wound. Seen for the first time on Jan. 1, 1902, at St. Joseph's Hospital, a large ulcer being present at the site of vaccination. No other lesion on the body. One week ago the muscles of the back became tender, though not stiff at that time. Four days ago the muscles of the back and neck were tender and rigid, and one day later the muscles of the jaw were fixed. There was on January 1 rigidity of the localities mentioned. Muscles were in a constant state of contraction, with occasional aggravation of the continuous spasms. No anesthesia or hyperesthesia. Visual field slightly contracted. On January 4 the abdomen was distended and its muscles rigid. January 6 to 9, clonic spasms greatly decreased. Muscles of the back of the neck rigidly contracted. Could almost open mouth to full extent. Heavy antitoxin dosage. Developed erythema of chest and legs, also a few pustules scattered over the surface. January 11, 12 and 13 showed a steady though slow convalescence. Slightly delirious at night. Left the hospital against advice Jan. 14, 1902. Treatment consisted in the use of antitoxin, chloral and bromids.

CASE 42.—, white, aged 8, was vaccinated in Chicago during 1900, with "city virus." An investigation of this and of the following case showed that the children had badly infected arms from lack of care and cleanliness. In this case a narrow bandage was placed around the arm, by the mother, soon after the child was vaccinated, and allowed to remain until the sore and bandage became so offensive to the smell that they sought the advice of a physician, who dressed and cleaned the arm. This was five weeks after the performance of vaccination. A few days later tetanus appeared. Ten thousand other children were vaccinated with this same lot of vaccine without any bad results.

CASE 43.—, white child, was vaccinated in Chicago, during 1900, with "city virus." Three other children were vaccinated in the family at the same time and with the same lymph, all had typical vaccinations and no bad results. The bed in which this child slept was filthy, and the arm was infected through a total want of cleanliness. The vaccine lymph is tested by the Chicago Health Department, both as to its potency and its purity in the department laboratory before using. A number of other cases occurred at the same time in children who had not been vaccinated.

CASE 44.—Miss S., adult, white, vaccinated in 1901, in Cleveland, with glycerinated lymph. Careful aseptic precautions were taken, and a shield was applied. Tetanus developed on the 15th day following vaccination and terminated fatally. The physician had many other very severe wounds from this lymph, but no other cases of tetanus. Antitoxin was used in large doses, but to no avail, the patient dying on the 7th day.

CASE 45.—E. T., white, male, aged 6, was vaccinated on Feb. 1, 1882, in Auburn, N. Y., by the City Health Board. Twenty days later (February 20 and 21) he had headache, stiffness in the neck and back, and spasms with grimacing and setting of the jaws. Pain in the stomach. The vaccine ulcer when seen was  $\frac{1}{2}$  inch in diameter, had clean-cut edges, and an inert surface. Patient for some days had had pains in front of arm and forearm, and lately cramps in this hand. Feverish and tendency to urinate frequently. Had slept none since the 20th. Temperature in axilla 102.3 F. From this time stiffness of the jaws continued. Convulsions every 15 minutes, at which time jaws were firmly set, opisthotonos present, and child screamed with pain. Upper extremities not involved. Calomel and whisky in large doses had a marked quieting effect. In 36 hours patient took about two quarts of whisky. Became rational, had no more severe convulsions, though there was a tendency to twitches unless the whisky intoxication was pushed. On February 25 was rational. Hand was cramped and little finger and thumb crossed. Symptoms of needles sticking him in temples and pain in top of head. Then gradual subsidence of all symptoms. Coarse râles over both lungs. Extreme exhaustion and long, tedious convalescence until March 12, when complete recovery seemed sure. In May, 1882, this patient had been treated by the same physician for tetanus following a wound in the foot. He was treated in the same manner with complete success. Both attacks were severe until the intoxication was secured by means of the whisky.

CASE 46.—"Case of tetanus after vaccination was seen by me, 7 years ago and in consultation. The tetanus developed a couple of weeks after inoculation. The vaccination wound was large and ugly-looking, with much swelling. The child was a boy of about 10 to 12 years, and gave all the usual symptoms of tetanus, and died in the third week after vaccination by bovine lymph. Of course, cleanliness was not then well understood and bacteriology in its infancy." (Letter from consulting physician.)

CASE 47.—J. H., male, white, aged 38, an inmate of the insane department of the Philadelphia Hospital, was vaccinated on Nov. 18, 1901, with dry points. No dressing could be kept in place over the wound. On November 19 the arm was swollen red and painful, with a necrotic patch in the middle of the site of vaccination. This was excised and the arm dressed. November 25, difficulty experienced in eating breakfast. When examined at this time the jaws opened about one inch with difficulty, neck stiff, and back rigid. Area of vaccination excised and cauterized. Condition became rapidly more pronounced during the day, and swallowing impossible. Fed by rectum. Treated with carbolic acid, cocaine, atropin, and morphia. Urine drawn by catheter. Temperature 97.4, pulse 93, and respirations 24; ranged to 98.4 F., 109 and 30. November 26 (1:30 a. m.), had first convulsion, and five more before 6 a. m. Then a series of lighter spasms, and death at 8 a. m.

CASE 48.—L. B., male, white, aged 45, an inmate of the same

department, was vaccinated on Nov. 8, 1901, with dry points, the vaccination being successful on the 14th. November 26, patient was reported with swollen painful arm. The dressing had been worn for a short time only. Necrotic patch in center of vaccine ulcer, greenish in color. Wound cauterized and dressed. Antitoxin (1,000,000 units) given as immunizing dose. November 27, a. m., jaws stiff, less and less controllable, and soon immovable. Neck stiff same evening. November 28, neck rigid, jaws rigid and  $\frac{1}{2}$  inch apart, abdomen tense. Swallowing almost impossible. Rissus sardonius present. Antitoxin (3,000,000 units) at 9 a. m., and again at 2 p. m. During the next 36 hours 16,000,000 units were given. Fed by rectum. Rallied only once after injection of serum. Constipated; retention of urine which showed evidence of nephritis. November 29 two convulsions, each about  $\frac{1}{2}$  minute in length. Died from exhaustion at 6:15 a. m., on November 30. Total antitoxin used 25,000,000 units.

CASE 49.—John W., white, aged 6, was vaccinated in Massachusetts on Sept. 10, 1901, under strict aseptic precautions. A light gauze sponge and a gauze bandage were applied, and strict directions given to return the child if the arm became sore. Three weeks before the physician was called to see the child he had a fully developed attack of tetanus. Attempts to discover the anaerobic germs in cultures and on the coverslip failed. There was a large ulcer, bathed profusely in pus. The arm had been grasped by some one during the second week following vaccination and the pustule broken. The mother had also substituted for the dressing one of her own, and when the child was seen the dressing had not been changed for a week, was "soaked in pus, stinking and dirty in the extreme." The tetanus symptoms continued at first with severity in spite of the use of antitoxin, but at length subsided and the boy slowly recovered. From the same lot of virus 40 children were vaccinated, of whom the only one to develop tetanus was the above. No other lesion or cause of entrance of the micro-organism could be found.

CASE 50.—M. McG., white, female, aged 5, was vaccinated on the arm with glycerinated points on or about June 7, in Philadelphia. No dressing was worn over the wound which was soon covered by a scab. The latter had been scraped off in some manner not ascertainable, and when seen by the physician there was a large suppurating ulcer at the site of vaccination. The arm had been very painful and much inflamed for some days. Tetanus developed on June 29, a. m., and the symptoms were very severe from the start, including trismus, rigidity, opisthotonos, and severe convulsions. Thirty-six hours before death (10 p. m., June 30) the child could walk, but complained of being stiff. Antitoxin, chloral, and bromids were used, but without seeming effect. The child lived near and played often in a stable. The autopsy showed no other lesion on the body. Congestion of the spinal cord was noted, but no other pathologic change was evident.

CASE 51.—M. K., white, male, aged 31, an inmate of the insane department of the Philadelphia Hospital, was vaccinated on Nov. 11, 1901, with dry points. Vaccination successful November 28. Dressing was retained on arm for short time only. On December 4 patient had stiffness of legs, and discomfort in eating breakfast. No stiffness of neck, but jaws could only be opened about one inch. While getting into bed had first convulsion, with opisthotonos. Sodium bromid and carbolic acid were used throughout the day (the latter gr. ii, hypodermically). Morphia and atropin hypodermically. During December 4 abdomen and back more and more rigid. Retention of urine. Two convulsions during the night. December 5 to 8, condition about the same, urine showing presence of carbolic acid. On December 9 jaws opened wider ( $1\frac{1}{4}$  inches). Abdomen very rigid. Patient exhausted. Pilocarpin ointment rubbed into loins. General condition better. December 14 jaws again stiffer, general condition the same. Lungs becoming involved. December 17 to 19, delirious at times and while being examined had acute maniacal attack, with an epileptiform convulsion, cyanosis, and death with a temperature of 99.2 F. The autopsy showed passive congestion and edema of the lungs. Slight broncho-pneumonia of the right side. Parenchymatous nephritis. Hydronephrosis with dilatation of both ureters. Nutmeg liver. The left (vaccinated) arm showed an ulcer surrounded by a livid area. No other marks on body.

CASE 52.—J. McC., male, white, aged 38, inmate of same department, was vaccinated on Oct. 27, 1901, with dry points of a different production from those used in the other three cases. Vaccination successful on November 2. Dressing had been worn for short time only. On November 12 was sent to the ward with a painful, swollen arm, the vaccine wound angry with a dark, gray slough in the center. Slough excised and arm dressed. Arm at this time slightly stiff. On November 15 marked stiffness or arm, jaws, but not of neck. No fever, no convulsion. Antitoxin (2,000,000 units). Wound again excised and cauterized, and curetted. November 16 antitoxin (4,000,000 units) at 10 a. m., and again at 12 m., 4 p. m., and 7 p. m. Carbolic acid hypodermically. During night of November 16 jaws tightly locked, the neck stiff, and swallowing almost impossible. Urine showed albumin and casts retention. Had three convulsions on the 16th and died at 12:05 a. m., on the 17th. All the convulsions were characteristic of tetanus. Total antitoxin given was 18,000,000 units, carbolic acid grain 1, and cocaine grain 1. The patient had worked every day in a yard the soil from which had previously given a culture of tetanus bacilli. He admitted often scratching his vaccine sore.

The above series does not include 18 cases that had "stiffness of the neck and jaws with a bad arm and whose symptoms disappeared under full doses of serum" that occurred also in the Philadelphia Hospital, and at about the same time. Two of the cases were in resident physicians who even excised their vaccine wounds. The symptoms were indefinite and may or may not have been tetanus, but in all probability were not. The writer saw such a case in a student who applied to him several days after vaccination with seemingly increasing stiffness of the jaws. He had read of some of the foregoing cases

and was convinced that he was also a victim. He was given a large immunizing dose of antitoxin at his own request and the symptoms rapidly disappeared. This case was also probably not one of tetanus, and in any event it is improper to include such in a serious analysis of the disease.

*(To be continued.)*

## GLIMPSES OF THE PRACTICE OF MEDICINE AND SURGERY IN BRITISH AND SPANISH HONDURAS.

N. SENN, M.D., PH.D., LL.D.

PROFESSOR OF SURGERY, RUSH MEDICAL COLLEGE.  
CHICAGO.

*(Concluded from page 1081.)*

### SPANISH HONDURAS.

Puerto Cortez, the principal seaport town on the Atlantic side of Spanish Honduras, is reached from Belize by boat in twelve hours. On the downward trip the steamers of the United Fruit Company make a short stop at Port Barrios. The larger part of the voyage is made in what is practically an inland sea made by the numerous islands, or keys, as they are called, situated some distance from the coast, constituting as they do a broken seawall. Port Barrios is a small dilapidated village notwithstanding it is the Atlantic terminus of the Guatemala Railroad. The cornerstone laid for a public building by the late General Barrios remains as he left it, but is beginning to show the effects of the ravages of the elements and the gradual decay of old age. Puerto Cortez is a strange little city, lining as it does the shore for more than two miles. It has only one street, which serves as a public highway and roadbed for the Honduras Railroad and mule cars. It has the bay in front and mangrove swamps in the rear. The population is made up of a few whites, negroes, Indians, Caribs and a mixture of the different races, the negro element being the predominating one.

Honduras is the largest of the republics of Central America. It was liberated from the Spanish yoke in 1821, and since that time amid many a revolutionary storm has maintained a republican form of government. It is sparsely settled, its entire population not exceeding 375,000. In its palmy days it had a number of cities with a population of over a hundred thousand, flourishing cities which are now only a heap of ruins or have their sites marked by little villages. The interior is mountainous, the coast fringed by fertile lowlands or mangrove swamps. It is in the latter locality that malaria does its deadly work throughout the entire year. The soil is fertile and yields a rich harvest from the coast to the mountain peaks. Its agricultural resources are immense and only await the intelligent and energetic tiller of the soil to bring prosperity to the country noted for its poverty. At an elevation of 2000 to 4000 feet the climate is equable and exhilarating, resembling June weather of the Middle States.

#### WHERE ONLY MAN IS VILE.

Nature has done everything for Spanish Honduras to make it a productive, prosperous country, but the inherent indolence of the natives has inhibited progress and financial prosperity. Teguaigalpa, with a population of 15,000, is the largest city. Puerto Cortez has a large floating population, its inhabitants ranging at different times and seasons of the year from 1000 to 2000. The modern buildings are few, most of the buildings being small, one-story shanties, without a trace of paint. The public buildings are a disgrace to the government. The house occupied by the highest official, the commandante, would be looked at with disfavor by the citizens of Chicago's Ghetto. The wharf is in such rickety condition that the captains of the steamers which touch here are very cautious in reaching the wharf for fear that if the vessel should strike it with any degree of force the whole structure and the adjoining warehouse might lose their foundation, as some of the pilings have been reduced to the size of a broom-stick by the destructive barnacles.

San Pedro, the principal city on the Honduras Railroad, is situated 36 miles inland from Puerto Cortez. If the train makes good time the journey is made in four hours. The iron rails of the little railroad have done service since 1868, which might account for the slow speed and the unmerciful jolting and bumping of the two passenger coaches in the rear of the freight cars. San Pedro has 7000 inhabitants, and is quite an important business center. The present governor of the province has carried into effect many progressive ideas which will prove of lasting benefit to the city. The city hall is a creditable building facing the new park; the ground floor of the building is occupied by the barracks and the provincial jail. The railroad extends from here to Piomenti, its western terminus, a distance of 18 miles. The principal article of export from this part of Honduras consists of the perennial yield of the numerous and productive banana fields.

#### A PARADISE FOR SPORTSMEN.

The sportsman finds here a genuine paradise. From the different stations he is within easy reach of monkeys, deer, parrots, tapirs, peccaries, wild hogs, armadillos, tigers, and a great variety of birds of plumage. This country is rife for a period of awakening which will be realized with the introduction of more northern capital and energy and the establishment of a more stable government. The frequent revolutions and the weak government are responsible for the delay of modern progress and the poverty of the people. The requirements of the natives are few; their ambition is limited. The scanty clothing is a matter of small expense, the forests and banana fields furnish them with food which they can obtain with little or no exertion. Man, like animals, adapts himself to his environments. The climate of the lower altitudes is depressing, which, coupled with the ever-present chronic malarial intoxication, antagonizes energy and limits the desires of the average natives to the very necessities of life.

#### PHYSICIANS.

Spanish Honduras has 97 licensed practitioners, including natives and graduates from the medical colleges of the United States and from almost all of the countries of Europe. The license to practice is obtained from the Board of Medical Examiners appointed by the government. All candidates must be graduates of a medical school. For the last two years there has been a medical school connected with the university in the capital city. As this city has only 15,000 inhabitants, it is very evident that the clinical advantages of the medical department must necessarily be inadequate. The better class of medical students obtain their professional education in the United States. It must be a source of regret to the practitioners of this country as well as to the outside medical world that so far no medical society has been organized. The limited railway facilities and the irregularity and inadequacy of the coast steamer service may explain the lack of any attempt to organize the medical profession upon a permanent basis. It is to be hoped, however, that efforts in this direction will be made in the near future. Many of the practitioners of this remote country are in possession of a clinical experience which if published would add much valuable material to our medical literature. I have never failed to find, in the different tropical countries that I have visited, many cases that were a complete puzzle to me, and I am sure our southern colleagues have had the same experiences when they visited the hospitals and clinics of the northern part of the United States. A trip to Central America or any other part of the tropics by any of our medical men can not fail in enlarging their fund of knowledge in everything pertaining to tropical diseases. For this and many other reasons it is very desirable that a closer relationship should be cultivated between the medical profession of the United States and of our Southern republics. A number of the most successful practitioners in Honduras are graduates from the medical colleges of the United States. Most of them are young men who have left their homes and their families with high expectations of reaping in a short time a financial success which would overshadow their hardships and recompense them for the additional risk to which they expose their lives. From what I have seen in the different parts of Central America of our graduates and their work

I find no reason to encourage our young men to seek this part of the world in search of fame or wealth. As long as the different countries remain in the dormant condition in which they are at the present time there is no incentive for such a haphazard undertaking. The few men who have done fairly well would have done much better in any of our prosperous cities in the North. With an increased influx of American capital and labor the conditions for the medical men will be improved.

#### NATIVE DOCTORS.

By native doctors I do not mean the natives who have obtained their medical education either at home or abroad, but the native medicine men, who lack not only a knowledge of medicine, but who are devoid of anything akin to education of any kind. These natural or lay medicine men are to be found everywhere in the larger cities and in every hamlet. They control the bulk of medical practice. The lower classes of Hondurians, regardless of their racial origin, are exceedingly superstitious. They believe in witchcraft and superhuman power in dealing with disease. The medicine men are shrewd in taking advantage of this weakness of their fellowmen and practice deception to an extent unrivaled by their kind during any part of the world's history, past or present. These men do not devote their whole time and attention to the healing of the sick. In common with their neighbors, they cultivate a little banana patch or take care of a few coffee shrubs, but

not lose his sense of original tact under such perverse circumstances. He had no difficulty in securing a machete, the national weapon and universal implement, which constitutes an essential part of the outfit of every native. This implement is made of the best of steel. When called into requisition for such an unusual requirement it was sharpened with especial care. The patient was requested to place the part of the finger he had consented to lose upon a block. The sharp edge of the machete was laid upon the part of the phalanx which had to be divided in order to complete the amputation. A sharp blow upon the back of the extemporized amputating instrument severed the bone and the operation was completed. The wound was washed with a solution of permanganate of potassium and dressed in a most primitive way. The patient was promptly relieved from his suffering and it is related that the resulting stump was an excellent one.

On another occasion the services of the native doctor in the same locality was requested for a difficult obstetrical case. The woman had been in labor for three days without any appreciable progress. The layman obstetrician found the head impacted in the pelvis. After examination he came to the conclusion that the distended perineum was the principal cause of the delay in the delivery of the child. He had no instruments with which to deal effectually with the mechanical obstruction. He regarded the case as one of special importance in which the instrument to be employed to secure

A native house.

they are always in readiness to answer a sick call by day or night. The charges for their services are commensurate with their lack of medical knowledge. Two reals (10 cents) is considered by them a liberal fee for anything they are called upon to undertake. The capital invested for plying their trade is small. Charms of the cheapest kinds and a few herbs gathered in the jungles is all that is required to establish their business. They are general practitioners and have no use for specialists. They cover the entire field of medicine, surgery, gynecology and obstetrics. It will suffice if I quote a few instances of the practice of these native medical men. On one occasion in a hamlet not far from Puerto Cortez, a laborer became afflicted with a severe attack of parathium or felon. The distal phalangeal end of one of the fingers became seriously involved and it became a question whether or not it could be saved. The treatment pursued was powerless in arresting the ravages of the disease. The doctor as well as the patient became satisfied that the only proper treatment would consist in sacrificing the diseased part of the finger. The native physician undertook the task, but failed in making the necessary preparations to complete the undertaking. An ordinary pocket knife was sharpened and with it the soft tissues were incised on the proximal side of the disease down to the bone by a circular cut. The unexpected difficulty now arose—the bone had to be divided. A search through the entire village failed to produce an instrument suitable for this part of the primitive operation. The native doctor did

Only street in the City of Puerto Cortez.

the much-needed relief should be one made of precious metal. He found, after a long search, an old Spanish silver coin. One-half of its circumference was sharpened and with this instrument he incised the perineum in the median line with the result that soon after a living child was born. He sutured the wound with an ordinary sewing needle armed with cotton thread and found his patient two weeks later attending to her usual household duties. The natural healer in Honduras has before him a wide sphere of action, but his cash income is a very limited one, as the people gauge his services without reference to learning or skill, but on the basis of ordinary labor.

#### HOSPITALS.

There are only two small hospitals in the whole country, one in San Pedro and the other in the capital city. The *Hospitale Generale del Norte* at San Pedro is a two-story frame building formerly used as a protestant school for children. It can accommodate thirty patients. The large ward on the first floor is occupied by male patients. The furniture is of the simplest kind, iron bedsteads, seagrass mattresses, with a blanket and pillow and no linen. The male ward contains 24 cots and the adjoining female ward six. The operating room is supplied with a rough wooden table, no instruments or facilities for aseptic work. No provision is made for private patients. The physician in charge is appointed by the government and receives a small salary. He occupies the second story of the building. There are no

trained nurses, the convalescents do what they can for those who are confined to bed. The second hospital is located in the capital city. Its capacity is larger, but the facilities are in all probabilities of the same primitive character.

Spanish Honduras makes no provision for the insane. As long as the lunatics are harmless they are permitted to roam about and when they become dangerous they are imprisoned with criminals of all sorts.

#### A HONDURIAN MILITARY HOSPITAL.

The Hondurian soldier does not lead a life of luxury. He stands low in the social scale. He does not feel like a soldier; at any rate, he manifests no indications of a martial spirit. He enters the service of his country not by his own free will. Every able-bodied man of military age is drafted and must perform military duty three months every year, and when he becomes a reserve he must drill every Sunday morning until he reaches the age of forty-five. The reasons for the unpopularity of the military service in Honduras are very apparent. In the first place, the natives lack that essential quality of a good soldier—patriotism. The soldier's pay is so insignificant that it could be no inducement whatever to enter the service. The privates are paid ten cents a day and with this beggarly salary he must fight starvation the best he knows how, as he receives no rations. When he enters the service he receives a uniform made of cheap blue cotton cloth embellished by blood-red strips of cloth of the same quality, and when this is worn out he must clothe himself. The consequence of this miserly treatment of the soldier by the govern-

A Hondurian Military Hospital.

ment is that in the barracks and upon the streets he makes the appearance of a beggar or tramp and not of a soldier. The army has no distinctive head dress. The cheapest straw and felt hats and all kinds of caps are worn, which, with the bare feet and faded, ragged clothes, makes a picture not well calculated to infuse love for the country or to inspire a military spirit. The weapon used is a single breech-loader of ancient pattern kept in a most dilapidated condition. The dozen cartridges each man carries are kept in a small bag which is tied to the barrel of the rusty musket. The soldiers are distributed all over the country, seldom more than one hundred being at any one place. I was very much amused one Sunday morning at San Pedro where I had an opportunity to witness one of the weekly drills of the reserves. The men, all of them from thirty to forty-five years of age, came in their civilian Sunday clothes. None of them presented a church-going appearance. A more motley crowd it would be difficult to imagine. Most of them were supplied with wooden guns of their own make. The pieces, none of them alike, faintly resembled the outlines of a real gun. Others, who had not taken the time or pains to prepare a toy gun, drilled with sticks, some were empty-handed and only a very few were in possession of rusty guns that had done service years ago, but which in the present state would not prove more harmful in active service than the wooden imitations. No wonder the Hondurian soldiers have to be pressed into service and when in the military grasp of the country often seek relief by desertion or by feigning disease. The government makes no provision for the sick soldier. In case

of illness he must take care of himself and when this is out of question he has to depend on the mercy of his comrades, sick and well. The Hondurian Military Hospital I intend to describe is located in Puerto Cortez. It is the refuge for the sick of the local military force, which does not exceed one hundred men. It is an old, one-story, delapidated frame building, raised from the ground by piling. The stilts of wood which support the building are rotten and ready to give way under the slightest unusual provocation. The wooden stairs to one of the front doors have disappeared long ago. The same fate awaits any day the remaining access to the interior of the building. One thing this building does not lack, that is free ventilation. The many cracks and holes in the floor, ceiling and walls furnish free and multitudinous avenues for the entrance and escape of air. The front room is occupied by the guard. Here I found at the time of my visit two rusty muskets with fixed bayonets, each of them supplied with a little bag of ammunition fastened to the piece with a string. A large shelf, four feet from the floor, with a slight inclination and divided into six equal compartments by boards four inches in height with a smooth round block of wood at the head of each compartment answers the purpose of beds for the men in charge of the invalids. In the next room are beds of similar construction for the sick. This room was occupied by six patients, one of them in the midst of a severe malarial chill. There were no signs of blankets, sheets, pillows, towels or any other of the necessary conveniences of a sick room. When I stepped into the back room the floor threatened to give way. This room serves as a kitchen and dining room. A little pile of stones with a glimmering fire on top constituted the stove. I could find no trace of food supply. A rough table was the only article of furniture. No operating room and no dispensary existed. We were informed by the inmates of the hospital that the only medicines used in this hospital are castor oil and quinin. All of the patients were anemic and showed other signs of malarial intoxication.

#### PREVALENT DISEASES.

The prevailing diseases of Spanish Honduras are the same as those of British Honduras, as there is a great similarity of soil and inhabitants in both countries. Typhoid fever is almost unknown. The frequency with which dysentery and bowel affections occur would naturally lead us to expect that appendicitis is very common. This is, however, not the case. Dr. Austin, of Puerto Cortez, who has lived in Honduras for nine years and who has had an unusually large experience, never saw a case of appendicitis during this time, and his observation must be accepted as correct, as elsewhere he has had a very large experience with this disease. Tuberculosis in its various forms is rapidly decimating the natives. Diphtheria is almost unknown on the Atlantic coast. A case recently occurred at Rio Blanco, a village on the railroad between Puerto Cortez and San Pedro, and this was the only case that occurred in that part of the country. The patient was a little girl, white, five years of age. The diagnosis was confirmed by the paralysis of the soft palate which followed as a sequel to the membranous inflammation of the tonsils and pharynx. For a time the disease threatened laryngeal invasion. Fifteen units of the antitoxin was promptly followed by improvement and complete recovery. The little patient was isolated and no other cases developed. The source of the infection could not be traced. Pneumonia is of a comparatively mild type. Rheumatism and bronchitis are common diseases. The pernicious form of malaria is treated by the subcutaneous administration of heroic doses of quinin. Dr. Austin informed me that it is not unusual for him to administer 300 grains in the course of twelve to twenty-four hours.

#### STRYCHNIN TREATMENT OF SNAKEBITES.

Dr. Austin has great faith in the subcutaneous use of large doses of strychnin in the treatment of the bites of poisonous snakes, in fact he considers this remedy in the light of a specific, provided the treatment is commenced in time. The snake poison paralyzes the heart's action and in preventing this effect by the use of strychnin time is gained for the elimination of the poison. He injects subcutaneously one-twentieth grain of the drug every fifteen or twenty minutes until the

paralytic effect of the poison is neutralized. A moderate single dose of whisky or brandy is given during the beginning of the treatment.

In conclusion, I desire to thank Mr. Henry M. Keith, Drs. Eyles and Harrison, of Belize, Dr. Austin, of Puerto Cortez, and Drs. Waller and Hunter, of San Pedro, for the many courtesies extended to me and my companion during our short and pleasant visit in British and Spanish Honduras.

## THE PROPOSED CONSTITUTION AND BY-LAWS FOR STATE SOCIETIES.

A Committee on Constitution and By-Laws was recently appointed by the President of the American Medical Association, Dr. John A. Wyeth, in accordance with a resolution adopted at the meeting of the Association at St. Paul last June, to coöperate with the committees on reorganization that have been or may be appointed by the various state societies. There has been an expressed desire on the part of the officers, members and committees of nearly all the state societies to comply with the recommendations of the American Medical Association in regard to a more uniform organization of the state bodies. The committee has thought best to prepare a constitution and by-laws for state societies that shall incorporate the general principles recommended to and adopted by the American Medical Association and it submits below such constitution and by-laws.

The committee desires it to be understood that this is only suggestive. While it believes that, as a rule, practically all the articles, chapters and sections can be adopted by most of the state societies, at the same time local conditions may make it advisable to modify them in various ways.

As will be noticed, the word "association" has been adopted as applying to the state body and the word "society" applying to the county. This is a minor detail and yet one of more or less importance. It has been adopted by Alabama and by some of the other state organizations.

In Article IV the committee has made no provision for honorary or associate members.

In Chapter IV, Section 2, provision is made for an apportionment of one delegate for every one hundred members. This may be too high in those states in which there are no large county societies. The object is to make the legislative body as small as is consistent with conditions, and in those states in which there is a large county society, a high apportionment makes it impossible for the large societies to get a controlling interest in the legislative body.

The name "House of Delegates" has been adopted in this constitution, but it is not necessarily to be followed, the name being immaterial.

The committee desires especially to call attention to the "council" provided in Chapter VII of the by-laws. As will be noted, this council is to be composed of men from various parts of the state, so that each part shall be fairly represented in this important body. It presupposes the division of a state into say ten districts, and in each of these districts a district society may be formed if it is thought best. Each individual councillor will have certain definite duties to perform. First, he is the censor for his district; all disputes between

members, between societies and between societies and members should be referred to the councillor and it will be his duty to settle such disputes if he can. It will be his duty to organize societies in counties in which none exist and to stimulate to active work societies now existing, or that may be created, and to visit each society at least once annually. If the right men are selected for the position of councillor, it will probably do away with the necessity of employing a paid organizer. The committee is earnest in its belief that such councillors should be paid their actual expenses in this work, believing that it will be money well invested from a financial point of view, and especially believing that medical men ought not to be asked to do such work for nothing and pay their own expenses. The majority of the committee believe that this council should have greater duties than have been given in this constitution: that it should be also the executive committee of the state society—in fact, that it should act for the state society during the interval between meetings. This suggestion is made, but it will be noticed that it is not incorporated in the by-laws. The committee believes that there should be a more or less continuous body in each state association. The probability is that the House of Delegates may be made up of entirely new members some year from what it was the year previous, and hence the necessity of a continuous body in the House of Delegates. The council is therefore made a part of the House of Delegates and its members are elected for five years. It is asked that this idea of a council be given special thought by the committees on reorganization representing the state societies.

The committee regards the creation of such a council made up of the truest, most unselfish, most willing, and most capable physicians in each state as of the very highest importance in the scheme of perfected organization. The council can, if in good hands, accomplish wonders for the profession. We beg that each state will give this innovation its most serious attention. It may be added that in those states in which it has been tried in part it has worked excellently well.

Attention is asked to the fact that the constitution is made very short and that it contains the essential features of the new mode of organization. The by-laws, on the other hand, contain the superstructure of regulations that have been built upon the constitution as a foundation. The committee believes that the provisions of the constitution are fundamental, and recommends that the state societies adopt them with just as little change as may be necessary to adapt them to local conditions. In the by-laws the committee has included much that is perhaps to be regarded as suggestive and more that is educational in its purpose. It follows then that the by-laws may be considerably modified in each state without damage to the uniformity of state organization which the American Medical Association has declared to be desirable.

There are sections in the by-laws that can be left out without difficulty, and beyond doubt many of the state committees will be able to suggest points that should be covered in the by-laws in order that the medical profession may be harmoniously and strongly organized. The

committee especially requests that each state committee, after full consideration of the documents herewith submitted, will transmit to this committee promptly those modifications which to them appear desirable. In this way the work of organization may be kept going with equal facility and simultaneously in all parts of the country, and by this means each state can be given the early opportunity of taking under consideration the ideas and plans of its near and distant neighbors. It will then be perceived that this committee regards it as highly important to the general welfare that all the state societies should in all things work in mutual harmony, and should be furnished the facilities for the ready intercommunication of views. Up to this time each state medical society has been an isolated community working along similar lines, but each compelled to meet the same difficulties without the great advantage of having at hand the record of experience of sister societies under like circumstances. The new scheme of medical organization has as one fundamental principle the federating together of the state societies. The execution of this ideal will never be of greater service than under present conditions, when each state is anxious to perfect its mode of organization.

Section 8 of Chapter IV of the by-laws is objected to by some, but the principle expounded is indubitably correct; the method of execution can no doubt be improved upon by the state committees. The same remarks hold true as to Section 12 of Chapter XII, and again the principle is one that is too important to be overlooked.

The committee has suggested that the annual dues be two dollars. The profession can profitably employ all the funds that can be raised without putting a burden on its members, but there must be a sufficient amount to render effective the work of the association. Money is essential to the success of any sort of organization, and physicians should learn that liberal contributions to well-conducted medical societies will bring tenfold benefit. Each society might well contemplate the creation of an endowment fund to be held, invested, used in emergencies of legislative contest or scientific research, or the interest applied to special purposes. Massachusetts has accumulated in this way \$47,200. Other states can readily make a beginning and the value of such a fund as a factor in stability and as a help in emergency is simply incalculable. Above all, medical societies should gather funds to assist scientific research by direct grant of funds or by offering rewards. By doing this we will aid the forward movement of medical science, and will also convince the general public that our protestations of concern for the general welfare are genuine.

Much in the by-laws submitted may be regarded as "preaching," but it is inserted advisedly, with the sole object of arousing in the minds of each medical society member a desire for the accomplishment of greater ends than has been permitted by the customs and forms of the past. The committee earnestly desires that the state committees will continue the work of perfecting organization, actuated by that love for our profession that its ideals demand. With the medical profession well organized, medical science will more rapidly step to its appointed high place, and the profession which lives in its atmosphere will have that power and respect in the community that is its right.

J. N. McCORMACK, Bowling Green, Ky..

P. MAXWELL FOSHAY, Cleveland, Ohio.

GEORGE H. SIMMONS, Chicago, Ill.

*Committee.*

## CONSTITUTION.

### ARTICLE I.—NAME OF THE ASSOCIATION.

The name and title of this organization shall be the  
——— State Medical Association.

### ARTICLE II.—PURPOSES OF THE ASSOCIATION.

The purpose of this Association shall be to federate and bring into one compact organization the entire medical profession of the State of ———, and to unite with similar Associations in other States to form the American Medical Association; with a view to the extension of medical knowledge, and to the advancement of medical science; to the elevation of the standard of medical education, and to the enactment and enforcement of just medical laws; to the promotion of friendly intercourse among physicians, and to the guarding and fostering of their material interests; and to the enlightenment and direction of public opinion in regard to the great problems of state medicine; so that the profession shall become more capable and honorable within itself, and more useful to the public in the prevention and cure of disease, and in prolonging and adding comfort to life.

### ARTICLE III.—COMPONENT SOCIETIES.

Component Societies shall consist of those county medical societies which hold charters from this Association.

### ARTICLE IV.—COMPOSITION OF THE ASSOCIATION.

SECTION 1. This Association shall consist of Members, Delegates and Guests.

SEC. 2. MEMBERS. The Members of this Association shall be the members of the component county medical societies.

SEC. 3. DELEGATES. Delegates shall be those members who are elected in accordance with this Constitution and By-Laws to represent their respective component county societies in the House of Delegates of this Association.

SEC. 4. GUESTS. Any distinguished physician not a resident of this State may become a guest during any Annual Session upon invitation of the Association or its Council, and shall be accorded the privilege of participating in all of the scientific work for that Session.

### ARTICLE V.—HOUSE OF DELEGATES.

The House of Delegates shall be the legislative and business body of the Association, and shall consist of (1) Delegates elected by the component county societies, and (2), *ex-officio*, the officers of the Association as defined in this Constitution.

### ARTICLE VI.—SECTIONS AND DISTRICT SOCIETIES.

The House of Delegates may provide for a division of the scientific work of the Association into appropriate Sections, and for the organization of such Councillor District Societies as will promote the best interests of the profession, such societies to be composed exclusively of members of component county societies.

### ARTICLE VII.—SESSIONS AND MEETINGS.

SECTION 1. The Association shall hold an Annual Session, during which there shall be held daily not less than two General Meetings, which shall be open to all registered members, delegates and guests.

SEC. 2. The time and place for holding each Annual Session shall be fixed by the House of Delegates.

### ARTICLE VIII.—OFFICERS.

SECTION 1. The officers of this Association shall be a President, three Vice-Presidents, a Secretary, a Treasurer, and ten Councillors.

SEC. 2. The President and Vice-Presidents shall be elected for a term of one year. The Secretary, Treasurer and Councillors shall be elected for terms of five years each, the Councillors being divided into classes so that two shall be elected each year. All of these officers shall serve until their successors are elected and installed.

SEC. 3. The officers of this Association shall be elected by the House of Delegates on the morning of the last day of the Annual Session, but no Delegate shall be eligible to any office named in the preceding section, except that of Councillor, and no person shall be elected to any such office who is not in attendance upon that Annual Session and who has not been a member of the Association for the past two years.

#### ARTICLE IX.—FUNDS AND EXPENSES.

Funds for meeting the expenses of the Association shall be arranged for by the House of Delegates by an equal per capita assessment upon each county society to be fixed by the House of Delegates, by voluntary contribution, and from the profits of its publications. Funds may be appropriated by the House of Delegates to defray the expenses of the Annual Sessions, for publication, and for such other purposes as will promote the welfare of the Association and profession.

#### ARTICLE X.—REFERENDUM.

The General Meeting of the Association may, by a two-thirds vote, order a general referendum upon any question pending before the House of Delegates, and the House of Delegates may, by a similar vote of its own members, or after a like vote of the General Meeting, submit any such question to the membership of the Association for a final vote; and if the persons voting shall comprise a majority of all the members, a majority of such vote shall determine the question, and be binding upon the House of Delegates.

#### ARTICLE XI.—THE SEAL.

The Association shall have a common Seal, with power to break, change or renew the same at pleasure.

#### ARTICLE XII.—AMENDMENTS.

The House of Delegates may amend any article of this Constitution by a two-thirds vote of the delegates registered at that Annual Session, provided that such amendment shall have been presented in open meeting at the previous Annual Session, and that it shall have been sent officially to each component county society at least two months before the session at which final action is to be taken.

#### BY-LAWS.

##### CHAPTER I.—MEMBERSHIP.

SECTION 1. All members of the Component County Societies shall be privileged to attend all meetings and take part in all of the proceedings of the Annual Sessions, and shall be eligible to any office within the gift of the Association.

SEC. 2. The name of a physician upon the properly certified roster of members, or list of delegates, of a chartered county society which has paid its annual assessment, shall be *prima facie* evidence of his right to register at the annual session in the respective bodies of this Association.

SEC. 3. No person who is under sentence of suspension or expulsion from any component society of this Association, or whose name has been dropped from its roll of members, shall be entitled to any of the rights or benefits of this Association, nor shall he be permitted

to take any part in any of its proceedings until such time as he has been relieved of such disability.

SEC. 4. Each member in attendance at the annual session shall enter his name on the registration book, indicating the component society of which he is a member. When his right to membership has been verified by reference to the roster of his society, he shall receive a badge which shall be evidence of his right to all the privileges of membership at that session. No member or delegate shall take part in any of the proceedings of an annual session until he has complied with the provisions of this section.

##### CHAPTER II.—ANNUAL AND SPECIAL SESSIONS OF THE ASSOCIATION.

SECTION 1. The Association shall hold an annual session at such time and place as has been fixed at the preceding annual session (or as fixed by this Constitution and By-Laws).

SEC. 2. Special sessions of either the Association or House of Delegates shall be called by the President at his discretion or upon petition of twenty delegates.

##### CHAPTER III.—GENERAL MEETINGS.

SECTION 1. The General Meetings shall include all registered members, delegates, and guests, who shall have equal rights to participate in the proceedings and discussions; and, except guests, to vote on pending questions. Each General Meeting shall be presided over by the President, or in his absence or disability, or by his request, by one of the Vice-Presidents. Before it, at such time and place as may have been arranged, shall be delivered the annual address of the President and the annual orations, and the entire time of the Session so far as may be shall be devoted to papers and discussions relating to scientific medicine.

SEC. 2. The General Meeting shall have authority to create committees or commissions for scientific investigations of special interest and importance to the profession and public, and to receive and dispose of reports of the same; but any expense in connection therewith must first be approved of by the House of Delegates.

SEC. 3. Except by special vote, the order of exercises, papers and discussions as set forth in the official program shall be followed from day to day until it has been completed.

SEC. 4. No address or paper before the Association, except those of the President and Orators, shall occupy more than twenty minutes in its delivery; and no member shall speak longer than five minutes, nor more than once on any subject.

SEC. 5. All papers read before the Society shall be its property. Each paper shall be deposited with the Secretary when read, and if this is not done it shall not be published.

##### CHAPTER IV.—HOUSE OF DELEGATES.

SECTION 1. The House of Delegates shall meet annually at the time and place of the annual session of the Association, and shall so fix its hours of meeting as not to conflict with the first General Meeting of the Association, or with the meeting held for the address of the President and the annual orations, and so as to give delegates an opportunity to attend the other scientific proceedings and discussions so far as is consistent with their duties. But if the business interests of the Association and profession require, it may meet in advance, or remain in session after the final adjournment of the General Meeting.

SEC. 2. Each component county society shall be entitled to send to the House of Delegates each year one delegate for every 100 members, and one for each major fraction thereof, but each county society holding a charter from this Association, which has made its annual report and paid its assessment as provided in this Constitution and By-Laws, shall be entitled to one delegate.

SEC. 3. A majority of the registered delegates shall constitute a quorum, and all of the meetings of the House of Delegates shall be open to members of the Association.

SEC. 4. It shall, through its officers, Advisory Council, and otherwise, give diligent attention to and foster the scientific work and spirit of the Association, and shall constantly study and strive to make each annual session a stepping-stone to future ones of higher interest.

SEC. 5. It shall consider and advise as to the material interests of the profession, and of the public in those important matters wherein it is dependent upon the profession, and shall use its influence to secure and enforce all proper medical and public-health legislation, and to diffuse popular information in relation thereto.

SEC. 6. It shall make careful inquiry into the condition of the profession of each county in the State, and shall have authority to adopt such methods as may be deemed most efficient for building up and increasing the interest in such county societies as already exist, and for organizing the profession in counties where societies do not exist. It shall especially and systematically endeavor to promote friendly intercourse between physicians of the same locality, and shall continue these efforts until every physician in every county of the State who can be made reputable has been brought under medical society influence.

SEC. 7. It shall encourage-post-graduate work in medical centers, as well as home study and research, and shall endeavor to have the results of the same utilized and intelligently discussed in the county societies. (With these ends in view, five years after the adoption of these By-Laws no voluntary paper shall be placed upon the annual program or be heard in the Association, which has not first been read in the county society of which the author is a member.)

SEC. 8. It shall elect representatives to the House of Delegates of the American Medical Association in accordance with the Constitution and By-Laws of that body in such a manner that not more than one-half of the delegates shall be elected in any one year.

SEC. 9. It shall, upon application, provide and issue charters to county societies organized to conform to the spirit of this Constitution and By-Laws.

SEC. 10. In sparsely settled sections it shall have authority to organize the physicians of two or more counties into societies to be designated by hyphenating the names of two or more counties so as to distinguish them from district and other classes of societies, and these societies, when organized and chartered, shall be entitled to all the privileges and representation provided herein for county societies, until such counties may be organized separately.

SEC. 11. It may divide the counties of the State into ten Councillor Districts, and, when the best interest of the Association and profession will be promoted thereby, organize in each a district medical society, to meet midway between the Annual Sessions of this Association, and members of the chartered county societies, and none others, shall be members in such district societies. When so organized from the presidents of such district

societies shall be chosen the Vice-Presidents of this Association, and the presidents of the county societies of the district shall be the vice-presidents of such district societies.)

SEC. 12. It shall have authority to appoint committees for special purposes from among members of the Association who are not members of the House of Delegates, and such committees may report to the House of Delegates in person, and may participate in the debate thereon.

SEC. 13. It shall approve all memorials and resolutions issued in the name of the Association before the same shall become effective.

SEC. 14. It shall present a summary of its proceedings to the last general meeting of each annual session, and shall publish the same in the Transactions.

#### CHAPTER V.—ELECTION OF OFFICERS.

SECTION 1. All elections shall be by secret ballot, and a majority of the votes cast shall be necessary to elect.

SEC. 2. The House of Delegates on the first day of the Annual Session shall select a Committee on Nominations consisting of ten delegates, no two of whom shall be from the same councillor district. It shall be the duty of this committee to consult with the members of the Association and to hold one or more meetings at which the best interests of the Association and of the profession of the State for the ensuing year shall be carefully considered. The Committee shall report the result of its deliberations to the House of Delegates in the shape of a ticket containing the names of three members for the office of President and of one member for each of the other offices to be filled at that annual session. No two candidates for President shall be named from the same county.

SEC. 3. The report of the Nominating Committee and the election of officers shall be the first order of business of the House of Delegates after the reading of the minutes on the morning of the last day of the General Session.

SEC. 4. Nothing in this article shall be construed to prevent additional nominations being made by members of the House of Delegates.

#### CHAPTER VI.—DUTIES OF OFFICERS.

SECTION 1. The President shall preside at all meetings of the Association and of the House of Delegates; shall appoint all committees not otherwise provided for; shall deliver an annual address at such time as may be arranged; shall give a deciding vote in case of a tie, and shall perform such other duties as custom and parliamentary usage may require. He shall be the real head of the profession of the State during his term of office, and, as far as practicable, shall visit by appointment the various sections of the State and assist the Councillors in building up the county societies, and in making their work more practical and useful.

SEC. 2. The Vice-Presidents shall assist the President in the discharge of his duties. In the event of his death, resignation or removal, the Council shall select one of the Vice-Presidents to succeed him.

SEC. 3. The Treasurer shall give bond for the trust reposed in him whenever the House of Delegates shall deem it requisite. He shall demand and receive all funds due the Association, together with the bequests and donations. (He shall, under the direction of the House of Delegates, sell or lease any estate belonging to the Association, and execute the necessary papers; and shall, in general, subject to such direction, have the care and management of the fiscal affairs of the Association.)

He shall pay money out of the Treasury only on a written order of the President, countersigned by the Secretary; he shall subject his accounts to such examination as the House of Delegates may order, and he shall annually render an account of his doings and of the state of the funds in his hands. He shall charge upon his books the assessments against each component county society at the end of the fiscal year; he shall collect and make proper credits for the same, and perform such other duties as may be assigned to him.

SEC. 4. The Secretary, acting with the Committee on Scientific Work, shall prepare and issue the programs for and attend all meetings of the Association and of the House of Delegates, and he shall keep minutes of their respective proceedings in separate record books. He shall be custodian of all record books and papers belonging to the Association, except such as properly belong to the Treasurer, and shall keep account of and promptly turn over to the Treasurer all funds of the Association which come into his hands. He shall provide for the registration of the members and delegates at the Annual Sessions. He shall keep a card-index register of all the legal practitioners of the State by counties, noting on each his status in relation to his county society, and upon request shall transmit a copy of this list to the American Medical Association for publication. In so far as it is in his power he shall use the printed matter, correspondence and influence of his office to aid the Councillors in the organization and improvement of the county societies, and in the extension of the power and usefulness of this Association. He shall conduct the official correspondence, notifying members of meetings, officers of their election, and committees of their appointment and duties. He shall act as Chairman of the Committees on Scientific Work and on Publication. He shall employ such assistants as may be ordered by the Council or the House of Delegates. He shall annually make a report of his doings to the House of Delegates.

In order that the Secretary may be enabled to give that amount of time to his duties which will permit of his becoming proficient, it is desirable that he should receive some compensation. The amount of his salary shall be fixed by the House of Delegates.

#### CHAPTER VII.—COUNCIL.

SECTION 1. The Council shall hold daily meetings during the annual session of the Association and at such other times as necessity may require, subject to the call of the Chairman or on petition of three Councillors. It shall meet on the last day of the annual session of the Association for re-organization and for the outlining of work for the ensuing year. At this meeting it shall elect a Chairman and Secretary, and it shall keep a permanent record of its proceedings. It shall, through its Chairman, make an annual report to the House of Delegates at such time as may be provided.

SEC. 2. Each Councillor shall be organizer, peace-maker and censor for his district. He shall visit each county in his district at least once a year for the purpose of organizing component societies where none exist, for inquiring into the condition of the profession, and for improving and increasing the zeal of the county societies and their members. He shall make an annual report of his doings, and of the condition of the profession of each county in his district to each annual session of the House of Delegates. The necessary traveling expenses incurred by such Councillor in the line of the duties herein imposed may be allowed by the House

of Delegates upon a proper itemized statement, but this shall not be construed to include his expense in attending the annual session of the Association.

SEC. 3. Collectively the Council shall be the Board of Censors of the Association. It shall consider all questions involving the rights and standing of members, whether in relation to other members, to the component societies, or to this Association. All questions of an ethical nature brought before the House of Delegates or the General Meeting shall be referred to the Council without discussion. It shall hear and decide all questions of discipline affecting the conduct of members or of a county society, upon which an appeal is taken from the decision of an individual councillor. Its decision in all such cases shall be final.

SEC. 4. The Council shall have the right to communicate the views of the profession and of the Association in regard to health, sanitation and other important matters to the public and the lay press. Such communications shall be officially signed by the chairman and secretary of the Council, as such.

#### CHAPTER VIII.—COMMITTEES.

SECTION 1. The standing committees shall be as follows:

A Committee on Scientific Work.

A Committee on Public Policy and Legislation.

A Committee on Publication.

A Committee on Nominations.

A Committee on Arrangement, and such other Committees as may be necessary. Such committees shall be elected by the House of Delegates, unless otherwise provided.

SEC. 2. The Committee on Scientific Work shall consist of three members, of which the Secretary shall be a member and Chairman, and shall determine the character and scope of the scientific proceedings of the Association for each session, subject to the instructions of the House of Delegates or of the Association, or to the provisions of the Constitution and By-Laws. Thirty days previous to each annual session it shall prepare and issue a program announcing the order in which papers, discussions and other business shall be presented, which shall be adhered to by the Association as nearly as practicable.

SEC. 3. The Committee on Public Policy and Legislation shall consist of three members and the President and Secretary. Under the direction of the House of Delegates it shall represent the Association in securing and enforcing legislation in the interest of the public health and of scientific medicine. It shall keep in touch with professional and public opinion, shall endeavor to shape legislation so as to secure the best results for the whole people, and shall utilize every organized influence of the profession to promote the general influence in local, state and national affairs and elections. Its work shall be done with the dignity becoming a great profession and with that wisdom which will make effective its power and influence. It shall have authority to be heard before the entire Association upon questions of great concern at such time as may be arranged during the annual session.

SEC. 4. The Committee on Publication shall consist of three members, of which the Secretary shall be one and Chairman, and shall have referred to it all reports on scientific subjects, and all scientific papers and discussions heard before the Association. It shall be empowered to curtail or abstract papers and discussions, and any paper referred to it which may not be suitable

for publication in the Transactions may be returned to the author. The Committee shall have authority to arrange for the publication and distribution of the Transactions after receiving competitive bids, and shall use diligence in getting them into the hands of the members. All papers read before the Association shall be the property of the Association.

SEC. 6. The Committee on Nominations shall be appointed and perform its duties in accordance with the provisions of Chapter — Sec. — of these By-Laws.

SEC. 7. The Committee of Arrangements shall consist of the component society in the territory in which the annual session is to be held. It shall, by committees of its own selection, provide suitable accommodations for the meeting-places of the Association and of the House of Delegates, and of their respective committees, and shall have general charge of all the arrangements. Its Chairman shall report an outline of the arrangements to the Secretary for publication in the program, and shall make additional announcements during the session as occasion may require.

#### CHAPTER IX.—ASSESSMENTS AND EXPENDITURES.

SECTION 1. An assessment of two dollars per capita on the membership of the component societies is hereby made the annual dues of this Association. The Secretary of each county society shall forward its assessment together with its roster of all officers and members, list of delegates, and list of non-affiliated physicians of the county to the Secretary of this Association thirty days in advance of each Annual Session (or on or before some specified date).

SEC. 2. Any county society which fails to pay its assessment, or make the reports required, on or before the date above stated, shall be held as suspended, and none of its members or delegates shall be permitted to participate in any of the business or proceedings of the Association or of the House of Delegates until such requirements have been met.

SEC. 3. All motions or resolutions appropriating money shall specify a definite amount, or so much thereof as may be necessary for the purpose indicated, and must be approved by the Council and House of Delegates on a call of the ayes and noes.

#### CHAPTER X.—RULES OF CONDUCT.

The principles set forth in the Code of Ethics of the American Medical Association shall govern the conduct of members in their relations to each other and to the public.

#### CHAPTER XI.—RULES OF ORDER.

The deliberations of this Association shall be governed by parliamentary usage as contained in Robert's Rules of Order, unless otherwise determined by a vote of its respective bodies.

#### CHAPTER XII.—COUNTY SOCIETIES.

SECTION 1. All county societies now in affiliation with the State Association or those that may hereafter be organized in this State, which have adopted principles of organization not in conflict with this Constitution and By-Laws, shall, upon application to the House of Delegates, receive a charter from and become a component part of this Association.

SEC. 2. As rapidly as can be done after the adoption of this Constitution and By-Laws, a medical society shall be organized in every county in the State in which no component society exists, and charters shall be issued thereto.

SEC. 3. Charters shall be issued only upon approval of the House of Delegates and shall be signed by the President and Secretary of this Association. The House of Delegates shall have authority to revoke the charter of any component county society whose actions are in conflict with the letter or spirit of this Constitution and By-Laws.

SEC. 4. Only one component medical society shall be chartered in any county. Where more than one county society exists, friendly overtures and concessions shall be made, with the aid of the Councillor for the District if necessary, and all of the members brought into one organization. In case of failure to unite, an appeal may be made to the Council, which shall decide what action shall be taken.

SEC. 5. Each county society shall judge of the qualification of its own members, but, as such societies are the only portals to this Association and to the American Medical Association, every reputable and legally registered physician who is practicing, or who will agree to practice, non-sectarian medicine shall be entitled to membership. Before a charter is issued to any county society, full and ample notice and opportunity shall be given to every such physician in the county to become a member.

SEC. 6. Any physician who may feel aggrieved by the action of the society of his county in refusing him membership, or in suspending or expelling him, shall have the right of appeal to the Council and to the House of Delegates.

SEC. 7. In hearing appeals the Council may admit oral or written evidence as in its judgment will best and most fairly present the facts, but in case of every appeal, both as a Board and as individual councillors in district and county work, efforts at conciliation and compromise shall precede all such hearings.

SEC. 8. When a member in good standing in a component society moves to another county in this State, his name, upon request, shall be transferred without cost to the roster of the county society into whose jurisdiction he moves.

SEC. 9. A physician living on or near a county line may hold his membership in that county most convenient for him to attend, on permission of the society in whose jurisdiction he resides.

SEC. 10. Each county society shall have general direction of the affairs of the profession in the county, and its influence shall be constantly exerted for bettering the scientific, moral and material condition of every physician in the county; and systematic efforts shall be made by each member, and by the society as a whole, to increase the membership until it embraces every qualified physician in the county.

SEC. 11. Frequent meetings shall be encouraged, and the most attractive programs arranged that are possible. The younger members shall be especially encouraged to do post-graduate and original research work, and to give the society the first benefit of such labors. Official position and other preferments shall be unstintingly given to such members.

SEC. 12. At (some meeting in advance of the annual session of this Association) each county society shall elect a delegate or delegates to represent it in the House of Delegates of this Association, in the proportion of one delegate to each (one hundred members) or fraction thereof, and the secretary of the society shall send a list of such delegates to the Secretary of this Association, at least ten days before the annual sessions.

SEC. 13. The secretary of each county society shall keep a roster of its members, and a list of the non-affiliated registered physicians of the county, in which shall be shown the full name, address, college and date of graduation, date of license to practice in this State, and such other information as may be deemed necessary. He shall furnish an official report containing such information, upon blanks supplied him for the purpose, to the Secretary of this Association, thirty days in advance of each annual session, and at the same time that the dues accruing from the annual assessment are sent in. In keeping such roster the secretary shall note any changes in the personnel of the profession by death, or by removal to or from the county, and in making his annual report he shall be certain to account for every physician who has lived in the county during the year.

#### CHAPTER XIII.—AMENDMENTS.

These By-Laws may be amended at any annual session by a majority vote of all the delegates present at that session, after the amendment has laid upon the table for one day.

### New Instrument.

#### A NEW ASEPTIC THROAT MIRROR.

ALLEN T. HAIGHT, M.D.  
CHICAGO.

In presenting this aseptic throat mirror, made out of polished metal, it seems like a return to the time of flourishing Pompeii, when highly polished brass was used for hand-mirrors. The instrument is manufactured from German silver, highly nickel-plated. The handle is universal, is made out of steel, and the joint between the mirror and the handle is

a spring ball and socket, allowing mirrors of different sizes to be used. Being of solid metal, it can be rendered thoroughly aseptic by carbolizing or boiling without any deteriorating effect upon its polished surface. The mirror being nickel-plated, no acid will attack or corrode it provided the mirror is quickly cleansed after using.

Moist chromic acid, to the surface of the nickel-plate, has absolutely no effect. A metal throat mirror was first used by Dr. von Stein, of Moscow, in his clinic and private practice, his instrument being of polished steel. The steel was afterward nickel-plated, but neither of these proved a success. While in London this summer I had a set of instruments made after the pattern I suggested, making the mirror out of solid German silver highly polished and nickel-plated. I have been using the set in my office the last two months and have found the mirror satisfactory in every respect.

The advantages of this throat mirror over the ordinary one of glass are many. Besides those above mentioned, the ball and socket joint is of distinct benefit as the mirror is easily adjustable to any position or angle; there is no rim of metal to interfere with a perfect image being obtained from any part of its surface.

Mirrors are made with the plain or the concave surface. The latter mirror will be used more extensively by dentists. The expense of repolishing and nickeling these mirrors will be slight, and one set should last for many years.

In using the instrument the fingers must be kept away from the surface, and soft chamois skin should be used in polishing the surface before warming. When the mirror is to be used it should be adjusted to the proper angle, then dipped into hot water for a moment and the water allowed to run off and the instrument used before wiping it.

I believe this will be a valuable instrument not only for nose and throat specialists, but also for dentists. With it there can be no possible excuse for not having an absolute aseptic mirror.

**Clinical Thermometry.**—A trained nurse was recently talking in confidence about the ways of medical men and remarked among other things that nothing could exceed their carelessness in the use of the clinical thermometer. If one comes to think of it and to observe the ways of the average practitioner, one is compelled to acknowledge that the accusation has more truth than fiction in it. In the first place the sins of uncleanness have to be mentioned. Thermometers ought to be washed after removal from the mouth, or rectum, or elsewhere. That all doctors acknowledge. But how many cleanse their instruments in soap and warm water, with a final rinse in running, cold water and an hour's sojourn in 1-500 bichlorid? If this is said to be impossible, and the patient (best plan of all) is not able to provide his own, the doctor could at least carry two or three thermometers in his satchel or pocket, and not use the same one on two patients (except in emergency) on the same trip. Then there are the errors of observation. The thermometer is sometimes not shaken down before using. Or, believing the fond statement of the seller, the doctor thinks he has a "one minute" thermometer, and wonders again and again why so many of his patients have a subnormal temperature. As a matter of fact, for all mouth temperatures five minutes at least is required when the general American type of thermometer is used; and if the patient has recently been out in the cold, or has eaten ice-cream or drunk cold water, or is having a chill, the temperature of the mouth, as indicated by the instrument,

will continue to rise for ten or twelve minutes after the thermometer is put under the tongue. Axillary temperatures are still more unreliable. In case the patient has no rectal inflammation or congestion, rectal temperatures are most desirable. Far above all other indications, however, in clinical thermometry is the indication to use one's common sense in interpreting results.—*Pediatrics*.

**Drug Eruptions.**—There is scarcely any medicine which is not liable at some time to induce a cutaneous eruption, Bernard states in the *Gazette des Hôp.* Such eruptions assume all kinds of manifestations and generalization, but they can usually be differentiated by the absence of general symptoms commensurate to the severity of the cutaneous affections. Mercurial eruptions may be febrile and even malignant. Calomel is the most active in this respect. Fournier always tests the susceptibility of the patient to calomel before instituting vigorous treatment with it. Potassium iodid is liable to induce a multiple eruption exhibiting almost all the elementary cutaneous lesions. It may cause acne (especially in dyspeptics and persons inclined to acne), boils, pseudo-carbuncles, purpura, edema, vegetating pemphigus and primary or secondary gangrene, bunches resembling syphilitic gummata, ophthalmic zona, etc. Antipyrin may run the whole gamut of drug eruptions, but has one peculiar variety, the "stationary erythematopigmented eruption" with persisting brown patches. Gaucher has observed a fatal case of hemorrhagic copaliba erythema.

## SCHOOLS IN THEIR EFFECTS ON THE HEALTH OF GROWING GIRLS.

To the physician with a family practice, especially in the town or city, the effects of school life upon the health of girls is always a subject of great interest. Every year he is called on to combat the evil results of too much study and too little recreation. In children under nine or ten years of age, boys and girls have about equal endurance and there is no reason for employing different methods in their education. There is but little danger of overstudy at this time and the children usually exercise freely out of doors and obtain sufficient sleep. From about the tenth year, with the beginning of puberty, until development is complete at perhaps the eighteenth to the twentieth year, boys and girls should be dealt with educationally on quite different plans. During this period when the girl is finishing grammar school and is in high school, the most important thing is not to develop her brain to an extreme degree, but to develop her muscular system, her heart and lungs and to give her as nearly perfect digestion as possible. During this time of growth and development physical culture should be sought and given the first place in every consideration. The degree of physical perfection which is attained while the girl is passing through this period of physical growth will determine in a large measure her future health and usefulness. The mind can be cultivated later, and, since the mind matures later than the body, this is the natural sequence. Dr. Jane Kelly Sabine points out that menstrual irregularities are present in 75 per cent. of the women in finishing schools and colleges. These defects date to the time when menstruation first takes place, when habit neuroses are most easily formed, and the reconstruction in the girl's education must be made in the preparatory school. William H. Byford, in speaking of this matter many years ago, very aptly said: "Six hours' study and two hours' play should be reversed; it should rather be eight hours' unrestrained exercise and two hours' study." Laws have been enacted in many states to regulate the hours of labor for minors. If we calculate the hours spent in study in and out of school by many of the pupils in high school, the time would be far in excess of that allowed by law for the labor of minors; moreover, the work is more trying and fatiguing than mere physical labor.

A series of articles<sup>1</sup> on "The School and the Health of School Girls," recently written by four Boston physicians, makes profitable reading. The writers seem to agree that, during the time of puberal development there is a tendency to force the mental development of girls at the expense of the physical and that such a course leads to only bad results. The first step in correcting such a state of things is to locate the factors which unite to produce it, and here we find that blame rests upon both the school and the home. In the school there are too long hours, too much work required outside of school hours, lack of adaptation to the individual, competition among the scholars in examinations and systems of ranking.

In the home physical labor is very rarely of such a nature or quantity as to be injurious to the girl. More often harm comes from late hours with insufficient sleep. In girls who are older, social duties, parties, etc., with undue excitement, may be very detrimental. It is very difficult for a physician to convince parents of the evil results almost sure to follow if these various factors are allowed to operate upon the growing and developing girl. When a little later she becomes hysterical and unable to perform the duties belonging to a woman, people wonder why girls are not as strong as their grandmothers were. Parents are usually pleased when the school-teacher picks out their child as particularly bright and gives her extra work so that she may make two grades instead of one in a year. What difference does it make to a girl whether she graduates from grammar school or high school one or two years sooner or later? It does, however, make a vast difference whether she graduates with a well-developed and healthy body, ready to take up the serious duties of life or with a broken-down, nervous system which will require years to recuperate or which will handicap her during the remainder of life.

To remedy such a complex condition will not be easy. After physicians have pointed out the faults in the present system of education as applied to girls, it remains for educators to devise means for their correction. In educational matters, the opinion of a physician has much weight in a community, and he should make every effort to place school hygiene upon a proper scientific basis. This is one of the public duties which clearly devolves upon physicians because of their special training, and it can not be relegated to anyone else. Besides this, public duty to the girls of a community, the physician must also face the question as it applies to the individual girl. The family physician must never cease to warn parents of the dangers to which developing girls are exposed from overstudy, insufficient out of doors life and deficient sleep and he must make every effort to obtain as good physical development as possible for every girl, knowing that in so doing he is also making the best provision for mental growth and equilibrium.

## THE BACTERIOLOGY OF SYPHILIS.

Notwithstanding the probability that syphilis is dependent upon a bacterial cause, and despite the utmost industry in the search therefor, it can not be said with certainty that the specific agent has yet been isolated. The local invasion, the glandular enlargement, the period of incubation, the constitutional phenomena, the cutaneous eruptions, the gummata, all are the marks of an infectious disease. So many points of resemblance to other diseases of this group does syphilis present that it is likely often to be confounded with them unless one be constantly on his guard. By keeping this fact always in mind and by acquiring familiarity with the distinctive character of the lesions, the likelihood of error may be reduced to a minimum. The diagnosis once made, the treatment fortunately is clear and we have in mercury and iodine, alone or together, one of the few forms of specific medication. The need for serum-therapy does not, therefore, exist here as it does in connection with other infectious diseases. Nevertheless, the discovery of the micro-organism of syphilis would be a distinct advance, whose practical value can in the present state of knowledge scarcely be appreciated.

Some recent observations by Drs. Joseph and Piorkowski<sup>1</sup> are therefore worthy of attention in this connection. As they point out, a syphilitic but apparently healthy man, free from symptoms, may infect a healthy woman, as well as the embryo, in the act of impregnation. The likelihood of such infection is the smaller as the period from the beginning of the disease is the longer and the treatment employed has been the more active. For this reason the conclusion was reached that the syphilitic virus is contained in the seminal fluid, even when not discoverable elsewhere. Accordingly, a systematic study of this secretion was undertaken. For physiologic reasons, inoculation upon normal sterile placenta was practiced. Upon this medium there developed in 22 cases of syphilis seen at periods varying from 5 weeks to 3¼ years after the primary infection, plump bacilli from 4 to 8 microns long and from 0.2 to 0.3 micron thick, with bulbous extremities, staining well with carbolized fuchsin and gentian violet. The organism grew less well on syphilitic placenta. Cultivation upon bouillon and agar proved unsuccessful; nor could the bacilli be found upon uninoculated placenta. On the other hand the bacilli grown on placenta were susceptible of inoculation upon agar and especially upon urine-agar and upon blood serum. The bacilli coagulated milk and rendered it acid. They did not generate gas, but they formed indol in bouillon. They grew best at the temperature of the body and they gave rise to a moist, white, glistening deposit upon the surface of potato. The bacilli could not be found in the seminal fluid from four non-syphilitic men, nor in that from four syphilitic men examined from three to ten years after infection. In one case, however, bacilli were found five years after infection, but here cutaneous

lesions were still present. In experimental observations the bacilli failed to survive the spermatozoa, nor could the organisms be found when the seminal fluid contained no spermatozoa. The bacilli were found in the blood in two cases, namely one of azoospermia and one of recent infection. They exhibited agglutination with the blood-serum of infected individuals and they could not be isolated from the lesions of chancreoid. Further, they failed to induce disease in mice, guinea-pigs and rabbits, although suspicious lesions developed in inoculated swine.

It is impossible to decide as to the value of the foregoing observations without further evidence and, while the proof seems inadequate and the facts unconvincing, a final judgment must be reserved until the results recorded, together with their interpretation, are confirmed or refuted.

## THE PROPOSED CONSTITUTION FOR STATE SOCIETIES.

We print this week the constitution and by-laws outlined for state societies by the Committee on Organization of the American Medical Association. As is intimated in its introduction, there has been an expressed desire on the part of officials and committees of many of the state societies to coöperate in the work of uniform organization and to adopt a new constitution in conformity with the recommendations of the American Medical Association. But while the general principles recommended were appreciated, it seems to be difficult for some of the committees to embody these principles in the constitution and by-laws. Others seem to magnify the importance of some of the principles and to minimize the value of others. For these and other reasons there promises to be as much lack of uniformity in the future as there has been in the past, in spite of the universal desire that the opposite should be the case. With the constitution and by-laws now presented it is possible for all the state associations to have one plan, whose uniformity is so desirable, in fact so necessary, in performing the active work outlined for the future. While we do not doubt that each state association will be able to modify this constitution and by-laws in minor details to better fit local conditions, at the same time we believe that it is applicable even as it is to practically all the states. There are, of course, certain sparsely settled states and territories, such as, for instance, those of the western Rocky Mountain region, where organization by counties—and in some instances even by districts—is not only impracticable but unnecessary.

For the sake of emphasis we quote a paragraph from the committee's introductory, because it calls attention to a most important matter, the federation of state societies and as a result, coöperative work among them:

The committee especially requests that each state committee, after full consideration of the documents herewith submitted, will transmit to this committee promptly those modifications which to them appear desirable. In this way the work of organization may be kept going with equal facility and simul-

1. Berliner klinische Wochenschrift, March 24 and 31, 1902.

taneously in all parts of the country, and by this means each state can be given the early opportunity of taking under consideration the ideas and plans of its near and distant neighbors. It will then be perceived that this committee regards it as highly important to the general welfare that all the state societies should in all things work in mutual harmony, and should be furnished the facilities for the ready intercommunication of views. Up to this time each state medical society has been an isolated community working along similar lines, but each compelled to meet the same difficulties without the great advantage of having at hand the record of experience of sister societies under like circumstances. The new scheme of medical organization has as one fundamental principle the federating together of the state societies. The execution of this ideal will never be of greater service than under present conditions, when each state is anxious to perfect its mode of organization.

We hope those of our readers who are interested in the work of organization now in progress—which should include all who are interested in medicine—will read the report of the committee carefully and grasp the full meaning of all the provisions of the constitution and by-laws submitted. A thorough appreciation of these provisions will convince anyone that the profession of a state adopting these will have a machinery by which they can thoroughly organize themselves and, when organized, assist and coöperate with each other for the mutual good in various ways, and that by the adoption of the same machinery in adjunct states, the same coöperative work and mutual assistance can be carried on and on until we have an organized profession extending from the Atlantic to the Pacific and from the Canadian line to the shores of the Mexican gulf.

#### HIGH STANDARDS—A LAY OPINION.

To see ourselves as others see us is not always discouraging. The danger, in fact, is that sometimes it may give us too good a conceit of ourselves. Country doctors are not by any means always William McClures, but we think it probable that there are many of them who feel that they deserve some of the halo of saintship given him by the gifted Scotch clergyman. This is not profitable; self-consciousness of virtue has its ethical drawbacks. On the other hand, the current pessimism of some members of our profession is equally bad and sometimes worse. A physician who believes that the profession is going to the dogs is in danger of becoming reconciled to the belief and conducting himself accordingly, for humanity is weak and tends to adapt itself to its environment or what it believes it to be. A cynical pessimism has the very worst ethical prognosis and even a certain amount of priggery, which is by no means always hypocrisy, is in every way to be preferred, though it may be offensive.

We talk of commercialism pervading the profession and sometimes make ourselves believe that it predominates and that to the majority our code of ethics is obsolete both in letter and in spirit. That this is not the case no one ought to know better than ourselves, but outsiders sometimes emphasize this truth. In the last issue of one of the most widely circulated lay period-

icals of this country—*The Youth's Companion*—we find a grateful testimony to this effect which we can take to our comfort and profit. The editor says:

A young woman doctor was recently invited to become house physician of a woman's ward in a projected hospital. A large salary was assured to her, and opportunity for advanced experimental work in surgery. Investigation showed that the hospital was a purely money-making concern, based on extensive advertising. "Reputable physicians," was her brief comment, "have higher ideals than a large salary." Another physician, of assured standing, was recently approached by a pill company with an offer of a handsome sum of money if he would prescribe its pill once a day to each of his patients. "Show the gentleman out," was all the reply that was made to the suggestion. The family doctor is more and more giving way to the specialist, but it may be truly said that the ethics and standards of physicians and surgeons were never higher nor more unselfish than they are at the present day.

This is the honest judgment of a lay observer who takes a comprehensive view of us at our best. We ourselves know that abuses and evils exist and it would be foolish to ignore them if we wish to combat them. But there is a vastly greater amount of good if we would only see it; sometimes it is most prominently seen from the outside. Within the profession we have our view more or less obscured by the littleness and selfishness we see about us—they sometimes blind us to the many estimable qualities that exist even in those we criticize. It is well, therefore, to be reminded now and then that to outsiders the medical profession as a whole is still advancing toward its high ideals.

#### THE ESKRIDGE-PARKHILL MEMORIAL.

The Denver and Arapahoe Medical Society has published and sent out a beautiful memorial pamphlet to Drs. Parkhill and Eskridge, giving the addresses and remarks at the memorial meeting of the Society. It is fitting that this tribute to the leading neurologist and surgeon of the mountain regions should have been thus conceived and executed, and it will be so considered by the profession throughout the country. Drs. Parkhill and Eskridge were both men of mark and of far more than local reputation, and both in their personal and professional character well worthy the remembrance of their countrymen and colleagues.

#### COLORADO'S ATTITUDE TOWARD CONSUMPTIVES.

THE JOURNAL has in the past noted editorially the popular agitation—as shown in newspaper articles, etc.—to exclude consumptives from certain states and territories. This has aroused, it seems to us needlessly, the indignation of the health officers of Colorado, who have come out with a statement that no such rule has been contemplated in that state or even suggested by responsible citizens. We accept this correction as far as it is a correction and believe that the good sense of the legislators will prevent any such measures, which we have already been sure had no support from the responsible health officials of the state. Nevertheless it is a fact that such laws have been talked of; as Dr. John Inglis says in a communication to THE JOURNAL of March 1, there are many in Colorado who have gone

there for their health and regained it "who now advocate the passage of laws restricting others from regaining their health in the same way." It is only one of the evidences of the weakness of human nature.

#### THE FOURTH DISEASE.

It is almost two years since Clement Dukes called attention to what he designated<sup>1</sup> the "fourth disease." He believes this disease to be distinct from scarlatina, measles and rubella. Since the publication of Dukes' paper, the subject has been much discussed among British clinicians and the writers have been divided into two sets, one denying the existence of the "fourth disease" as an entity and recognizing the cases so described as only erratic instances of the well-known diseases, especially of scarlatina and rubella, while the followers of Dukes are equally convinced that the disease is a distinct and separate one. It is probably impossible to come to a conclusion of the controversy at present. The clinical course of the various eruptive diseases is so variable that different phases or forms of one disease might be looked upon as separate diseases, and every practitioner knows how difficult it is to be certain of the character of certain atypical cases, especially at the beginning of an epidemic. This fact is brought out in a recent article by Griffith.<sup>2</sup> The description of the "fourth disease" is so strikingly suggestive of scarlet fever that it would be safe for the present to class it as such and especially to employ all the prophylactic measures used in the latter disease. Until we are able to separate the eruptive disease by detecting the specific agent in each or by a specific biologic reaction, there will probably be cases which different observers will not agree to call by the same name.

#### SANITARY MISCONCEPTIONS.

The head of the health department of the city of Cleveland, Dr. Martin Friedrichs, recently gave a graphic and complete account of the method used by him in combating an epidemic of smallpox in that city last year. This was contributed to a popular monthly, as well as to medical journals, and has excited attention both on account of the novelty of some of the measures and their success. As is usually the case with medical matters described and discussed in non-medical publications, the newspapers have taken this up and drawn their own, sometimes erroneous, deductions therefrom. The disinfection and cleansing methods which were so effective in freeing infected localities from the active contagion have even been utilized by the anti-vaccinationists as an argument that smallpox is exclusively a filth disease and that compulsory vaccination was therefore not essential in combating the disorder. This seems to be the view taken by a St. Louis daily in a recent editorial, which is a fair sample of the style of quotation of authorities by anti-vaccinationists. It ignores the fact that vaccination had been general, but the virus was not always satisfactory and had aroused prejudice and resistance, and that the cleansing and formaldehyd fumigation was taken up as a last resort

for the riddance of smallpox infection where it existed. Dr. Friedrichs admits that the danger still exists and will exist till general immunity is secured by vaccination. A Chicago paper likewise shows the same tendency in one editorial while it rebukes it in another. On April 21 it called attention in a very sensible way to its St. Louis contemporary's fallacy and the next day spoke itself of "Cleveland, where Dr. Martin Friedrichs is battling against smallpox with a disinfectant as a substitute for vaccination." The ways of the lay journal in dealing with medical facts are often past finding out—at least beforehand.

#### THE TREATMENT OF SCARLET FEVER WITH THE BLOOD-SERUM OF CONVALESCENTS.

It does not seem unreasonable to hope that in the progress of time we may be provided with sera or antitoxins for the treatment of the various self-limited infectious diseases. Notwithstanding industrious examination, the exciting factors of the exanthematous diseases have as yet eluded detection. Until these are known it will be impossible to establish immunity artificially in such a way as to permit of the production of agents possessed of specific curative properties. Inasmuch, however, as the diseases under consideration terminate spontaneously, probably as a result of the generation and action within the body of antitoxic substances, and as one attack usually confers immunity against subsequent attack, it has been thought that curative effects could be obtained by the employment of the blood-serum of those convalescent from those diseases. Observations along this line have been made for several years at the clinic of Ernst von Leyden<sup>1</sup> in Berlin in the treatment of pneumonia, measles and scarlet fever, and the results, so far as they go, have been measurably satisfactory. The observations have been interrupted from time to time on account of lack of material, as either enough serum could not be accumulated or the cases came under notice at long intervals. Opportunity was afforded, however, for the treatment of a series of 16 cases of scarlet fever, principally in adults, the youngest patient being 12 years old. At first but 10 c.c. of serum was employed by subcutaneous injection, then 12 c.c., and finally, as it was found free from danger, 20 c.c. In three of the cases the results were brilliant, while in the remainder they were less positive. In general the course of the disease was shortened. This plan of treatment hardly commends itself on account of the natural difficulties in the way of obtaining the serum in sufficient amount and activity to be of practical and general utility. It is mentioned here only to mark one phase in the evolution of the important subject of serum-therapy.

#### SUGAR AND PROGRESS.

The statistics of the sugar consumption of the United States reported by the statistical bureau of the Treasury Department are striking enough to call for comment. From 33 pounds in 1870 the per capita consumption has risen to 68 pounds in 1901, an increase of more than double. This does not seem to take into account the other forms than cane and beet sugar; the immense

1. *Lancet*, July 24, 1900.

2. *Phila. Med. Jour.*, April 12; see abstract 25, p. 1110, *Jour. A. M. A.*, April 26.

1. *Deutsches Archiv für klinische Medizin*, 73 B., p. 616.

amount of glucose preparations, together with the fruit sugars, are apparently not reckoned. The average of sixty-eight pounds per citizen means that a very large number, probably a great majority, use a considerably larger proportion daily, the larger the number who take less, the larger the amount consumed individually by the remainder. It has been calculated that one-quarter of a pound of sugar per diem is about as much as can be safely included in a healthy diet, but this figure may be found too low. The progressive increase, as shown by the statistics of the last thirty years, if it continues a few years more, will bring us well beyond such a limit, and as it is, it is probably exceeded by hundreds of thousands at the present time. Their systems appear to be fairly able to dispose of it, so far as any definite information has been received. There may be some indigestion of saccharin origin, but diabetes mellitus and glycosuria are not notably on the increase. It is probable that an active person can safely get away with a very large amount of sugar in his diet and the noted fondness of the Anglo-Saxon people for sugar has been correlated by some authorities with their specially energetic race characteristics. The Western world got along without sugar for many centuries, but they were not the centuries of progress. The passing away of the dark ages coincided with the introduction of sugar into the diet of the European peoples, and there may be more in the connection than at first appears; it may have had its humble but still important share in the change. The unexampled progress of the nineteenth century may find part of its causation in the cheapness of sugar and the great extension of its dietetic use. This deduction may be far fetched, but not more so than some other conclusions drawn from statistics.

## Medical News.

### CALIFORNIA.

**More Plague in San Francisco.**—Another fatal case of plague was reported, April 20, in San Francisco, credited as having come from Davisville.

**Good Samaritan Hospital.**—Eight lots have been purchased recently at Los Angeles, to be used as a site for a new building for the Good Samaritan Hospital. The building and land will cost about \$64,000.

**New Chief Surgeon.**—Dr. Walter B. Coffey, who has been assistant to Dr. Gardner, chief surgeon of the Southern Pacific and Market Street railways, has been promoted to chief surgeon of the United Railways Company of San Francisco.

**State Organization of Health Boards.**—Representatives of various health boards in the state assembled at San Francisco, April 14, and effected a permanent organization with Dr. E. Von Adelung, Oakland, president, and Dr. J. A. Emery, San Francisco, secretary. A committee was appointed to formulate the rules of the new organization, whose purpose will be the betterment of sanitary and health conditions in all parts of the state.

**Do "Indian Doctors" Need License?**—It is reported from San Jose that W. Mohawk, "Indian medicine man," who was tried, April 9, before a jury in that city on a charge of practicing his profession without a certificate, was acquitted. The defendant could produce no authorization from the State Board of Medical Examiners, but was able to show to the satisfaction of the jury that the treaty existing between the United States and Indian tribes allowing those of the latter race to sell medicines prepared by them on their premises, exempted him from liability under the state law.

### GEORGIA.

**Passed for the Army.**—Dr. W. Hal Monerief, Atlanta, who served as assistant surgeon during the Spanish-American war,

has successfully passed his examination for the medical department of the Army.

**School Medical Examiners Organize.**—The medical examiners of the Atlanta public schools met, April 15, and organized, with Dr. Luther P. Stephens, president; Dr. Arthur G. Hobbs, vice-president, and Dr. L. L. Landrum, secretary.

**Georgia Pasteur Institute.**—The board of governors of this institute met in Atlanta, early in April, to hear the semi-annual reports of officers. The physician's report showed 39 cases treated, with no deaths. The patients came from the following states: Georgia, 27; Louisiana, 7; Alabama, 3; South Carolina, 1; Tennessee, 1.

**New Hospital Car.**—The Plant System shops in Savannah have turned out a hospital car for the use of the system, which is one of the most completely furnished cars of its kind in this part of the country. It will be stationed in Waycross and will form a part of every wrecking train sent out from that point. The car is divided into several compartments in which are placed an operating table, a hanging bed, so adjusted that the motion of the car will not be felt by the patient, a case for instruments and medicines, several stretchers, and, in fact, every appliance that might be of service in taking care of the injured.

### ILLINOIS.

**Personal.**—Drs. James H. Finch, Champaign, and Samuel M. Wylie, Paxton, sailed for Europe, May 1.—Dr. W. L. Karcher, Freeport, has returned from Philadelphia, and will be associated with Dr. Joseph H. Firestone.—Dr. Lewellyn B. Ashton, Quincy, has been appointed surgeon in the Illinois Naval Militia, with the rank of lieutenant (junior grade).

**Senate vs. House.**—In the sundry civil bill passed recently by the senate an appropriation was recommended for a new hospital building for Rock Island Arsenal, to cost \$16,500. The house committee did not decide favorably on this recommendation. The matter now goes to a conference committee, which it is hoped will pass this much-needed appropriation.

**County Must Pay.**—The Attorney-General has given a decision in the highly interesting contention as to the liability for smallpox charges which arose at the meeting of the supervisors, at Galesburg, recently. His opinion is against the supervisors, who believe that the charges should be paid by the townships in which the cases occur. The Knox County Board, in 1896, passed a rule that contagious diseases should be a township charge and that the county would not be liable therefor. The Attorney-General holds that the county can not pass such a rule for the purpose of relieving the county from liability and imposing the same upon the township.

### Chicago.

**Senn on Fenger.**—Dr. Nicholas Senn delivered an address before the students of the medical department of the University of Chicago, April 23, commemorative of the life of Christian Fenger.

**To Aid Hospitals.**—A musical and dramatic entertainment was given at the residence of Mrs. Potter Palmer, April 23, in aid of Maurice Porter and St. Luke's hospitals, which netted between \$600 and \$700 each for these institutions.

**Medicine Chests for Park Police.**—It is announced that Lincoln Park policemen are to be equipped with medicine chests that victims of accidents may be given aid quickly. The chests will be attached to the bicycles of the men.

**Structure of the Lung.**—Prof. W. D. Miller, of the University of Wisconsin, who has made special research in lung anatomy and circulation, lectured before the students and medical profession of the city at the Northwestern University Medical School, May 2, on "The Structure of the Lung and Its Blood and Lymph Supply."

**The Officer-of-the-Day Once More.**—The supply of recommendations is evidently being rapidly exhausted, but still the officers-of-the-day at Cook County Hospital during the past week have recommended: 1. That an additional ward be established for scarlet fever and diphtheria cases. 2. That each house physician and surgeon be clad in spotless white duck uniforms. 3. That a dressing-room be established in connection with the examining room. 4. That the wards be brightened by pictures. 5. That the system of ward cooks, recently inaugurated, be continued.

**Personal.**—Dr. Nicholas Senn, surgeon-general of Illinois, has been given leave of absence, and sailed, May 1, for Havre on *La Savoie*. He goes to Russia as a delegate to the International Red Cross, which meets in Moscow, this month.—Dr. Edmund

R. Moras was given a verdict against the West Chicago Street Railway Company of \$45,000 for injuries sustained by him six years ago, which resulted in the amputation of his left arm at the elbow.—Dr. William G. Stearns, formerly medical superintendent of the Illinois Eastern Hospital for Insane, Kankakee, and recently connected with the neurologic departments of Northwestern University Medical School, and the College of Physicians and Surgeons, has been appointed superintendent of the Sanatorium at Lake Geneva, Wis.—Dr. Cyrille Vermeren sailed for Antwerp, April 23, on the *Kensington*, for a four months' trip to Belgium, France and Germany.

#### KENTUCKY.

**In Memory of Dr. Cox.**—The Breathitt County Medical Society at its session in Jackson, April 21, passed resolutions of sympathy regarding the sudden and untimely death of Dr. Braxton D. Cox, Jr.

**Dinner to Dr. Kelly.**—In celebration of the success of the recent operation on Dr. Clinton W. Kelly's eyes, members of the medical profession of Louisville gave Dr. Kelly a dinner at the Pendennis Club, April 11.

**St. Anthony's Hospital Dedicated.**—The formal dedicatory exercises of St. Anthony's Hospital, Louisville, were held, April 15. The building contains 12 wards, 47 private rooms, 2 operating rooms, etc., is thoroughly equipped and has cost about \$100,000. The wards were opened for patients, May 1.

**Sale of Poisons Restricted.**—The druggists of Kentucky are in receipt of a communication from the State Board of Pharmacy, which calls their attention to recent legislative enactments of which they were not aware. The board encloses with its letter a copy of the pharmacy law of Kentucky as amended, March 17, 1902. The circular calls attention to the enforcement of the law against cocaine, and expresses the emphatic determination of the board to stamp out the cocaine evil. It then calls attention to section 11 of the law, which restricts the sale of poison to such an extent that it will be a difficult matter hereafter for anyone to purchase a deadly draught unless he can show good reason for its use. The section also rules against abortifacients, which have had a large sale.

#### MARYLAND.

**Johns Hopkins Endowment Fund.**—A meeting was held, May 2, at the Merchants' Club, Baltimore, to devise means to raise the balance of the \$1,000,000 needed for the endowment of the Johns Hopkins University. About \$700,000 has been raised, largely conditional on the raising of the balance of the \$1,000,000, which must be raised by July.

**Commencements.**—The College of Physicians and Surgeons held its annual commencement, April 29. There were 57 graduates out of a class of 63.—Baltimore Medical College held its commencement, April 29. The graduating class numbered 92. The address was delivered by Rev. Dr. Lewis, president of Western Maryland College, Westminster.

**Medical and Chirurgical Faculty of Maryland,** at its one hundred and fourth annual session, April 22, 23 and 24, elected the following officers: Dr. William T. Howard, president; Drs. Samuel T. Earle and Wilmer Brinton, vice-presidents; Dr. J. Williams Lord, secretary; Dr. Thomas A. Ashby, treasurer; Drs. Harry Friedenwald, J. McPherson Scott, and Samuel Theobald, with the president, secretary and treasurer ex-officio, executive committee. Dr. J. W. Chambers was elected a member of the board of trustees. The annual banquet was held at the close of the evening meeting, on April 24. Dr. E. Miller Reid was toastmaster. The title of Dr. James Tyson's annual address was: "The Present State of Our Knowledge of Diabetes Mellitus."

**Personal.**—Dr. Frank Cline Ferguson has resigned his position as assistant resident physician at Spring Grove Asylum for the Insane, and has gone to his home in Greenville, S. C., to practice.—Mrs. Louise Brack, who died recently in Baltimore, bequeathed \$1000 to St. Joseph's German Hospital.—Dr. and Mrs. Henry Barton Jacobs have returned to Baltimore and will spend the summer in Europe.—Dr. Leonard K. Hirschberg, of the graduating class of the Johns Hopkins Medical School, will sail for Europe, June 10. He will spend six months in German and French hospitals.—Dr. Joseph B. Saunders, coroner, Baltimore, fell and broke his right ankle, in attempting to reach the dead body of a boy who had fallen from a bridge.—Dr. T. E. Dwinelle is seriously ill from a fall received recently.—Dr. Arthur D. Mansfield sailed to-day for a summer tour of Southern Europe.

#### MISSOURI.

**Hospital Board Selected.**—The following board of managers has been selected for the new \$25,000 hospital, which A. R. Levering is building for Hannibal: Cyrus Albertson, George D. Clayton, John L. Schnitzer, P. D. Fisher, L. P. Munger, T. G. Dulany, Dr. John N. Baskett, J. T. Homle, Jr., and Matthew Quirk.

**Measles Epidemic.**—The city physician of St. Louis reports that there are several hundred cases of measles in St. Louis, and that more deaths have resulted from the malady in the past few weeks than from smallpox during the entire time of its prevalence in the city. He recommends that houses where the disease prevails be placarded as a warning to the public.

**Refused Vaccination.**—Warrants were issued at Jefferson City, April 22, for the arrest of Foreman A. H. Boiles and fourteen men employed by the H. F. Balch contracting firm at work grading the Colorado Railroad in this county, for defying the State Board of Health in refusing to be vaccinated. Smallpox developed recently in the railroad camps in Miller and Cole counties and the Board of Health of Cole county, backed by the State Board, ordered a general vaccination of all persons in the infected district.

**Abortion Advertisements.**—After a paper by Dr. John W. Kyger, read before the Kansas City Academy of Medicine on "The Decadence of the American Race," (see page 1185 of this issue) the Academy appointed a committee to draft resolutions expressing the feeling of the regular medical profession in regard to the abatement of one of the causes of this condition and asking for the co-operation of the profession throughout the United States. These resolutions, after commenting on the decrease in the American birth-rate, continue:

WHEREAS, Without a special effort to investigate, it must have been observed by the most indifferent with what flagrant violation of all sense of delicacy the public press gives place to advertisements of nostrums and means intended to prevent or cut short pregnancy: these advertisements appearing in a column of the paper set apart for such purpose under the name of "Personal Medical Advertisement," and referred to as "Guarantees," "Sure Relief," "Sure Prevention," etc., occupying in some Sunday editions of reputable papers as much as two columns, destined to fall into the hands of all classes, and

WHEREAS, We recognize the press as a most potent factor in the education of the masses, be it

*Resolved*, By the Academy of Medicine of Kansas City, Mo., that we respectfully recommend that a censorship over the public press should be exercised to the end of correcting such practice of publishing advertisements as those referred to in our whereases. Be it further

*Resolved*, That it should be deemed of sufficient moment for the attention of the Postoffice Department of the United States of America restricting or prohibiting the distribution of such papers, periodicals or magazines through the United States mail if they continue to so prostitute their columns with such matter.

These resolutions are being sent to all the state medical associations.

**Gregory Banquet.**—Representative medical men of the middle west, numbering 350, assembled at the Planters' Hotel, St. Louis, on April 17, to celebrate the 78th birthday anniversary of Dr. Elisha Hall Gregory, of that city, and to honor him on the completion of fifty years of service as a teacher of medicine. The occasion was most felicitous. An editorial on the subject will be found in THE JOURNAL of April 26. The program of toasts was as follows:

"The Physician as a Citizen," Dr. A. M. Dockery, Governor of Missouri.

"An Organized Profession," Dr. Jonathan E. Tefft, Springfield, Mo.

"Greetings from Chicago," Dr. Harold N. Moyer, Chicago.

"The Evolution of Surgery," Dr. De Forest Willard, Philadelphia.

"American Surgery," Dr. Warren B. Outten, St. Louis.

"The Medical Press," Dr. George H. Simmons, Chicago.

"Our Teacher," Surgeon General Walter Wyman, Washington, D. C.

"The Teacher in Medicine," Chancellor W. S. Chaplin, St. Louis.

"The Medical Profession of Missouri," Dr. Jefferson Davis Griffith, Kansas City.

"The St. Louis Medical Society," Dr. Norman B. Carson, St. Louis.

"Ethical Ideals," Dr. William G. Moore, St. Louis.

"Dr. Gregory as a Friend," Simon Pollak, M.D., St. Louis.

Dr. Charles H. Hughes, St. Louis, presented the honored guest with a handsomely bound memorial containing the signatures of all those present. He said that it contained "the sign manual of tender and loving hands, inscribed in affectionate remembrance of your personal regard for many of us in days ago, when some of us especially needed friends. It attests also their appreciation of your personal and professional worth and fidelity, in all the varying demands of your dutiful life."

Dr. Gregory responded to the toast, "Our Guest." He said: "This is a banquet of good humor—a love feast. I am now in the midst of my great students, their renown international. Your pleasure is my happiness; your success, my pride; your gratitude, my jubilee. How intimate the relationship of pupil and preceptor; their wishes, their sympathies, their successes are inseparable. The successful teacher must have docile pupils. Instructor and learner share alike—reciprocal. Gifted students make famous colleges." Dr. Gregory then emphasized that character is a necessary foundation in the pupil for the teacher to build upon. He contrasted old and new methods of teaching, and his words gave many an insight into his own character and personality.

Governor Dockery said, among other things: "Doctor Gregory was my friend in the days of young manhood; indeed, the friend of every man, notably the young man, struggling to achieve success in life. His example and his counsel lighted up many a dark place in life's young pathway."

Chancellor Chaplin thanked Dr. Gregory "for his services as a citizen, his pure life, his high ideals, for his honest efforts. They have made him a valuable citizen in this community. Then we thank him for his manner—manner is much of the man—his ready sympathy, his full appreciation, his hearty stimulation and encouragement. These have made him dear to us. I have never heard a man say an unkind word of Dr. Gregory. I have never heard Dr. Gregory say an unkind word of any human being. We thank him, then, for what he has done and for what he is doing. We thank him for what he has been and for what he is."

Dr. W. C. Moore asked: "What is the magnet that has drawn men from hundreds of miles away, leaving their business, leaving their demands and occupations, to be present at this board to-night? Is it that he is a great surgeon? There are surgeons who can do, and have done, and will do, all that he can with the scalpel and ligature. Is it that he is a great teacher? There are other teachers dividing honor and affection with him. Is it that he has for fifty years been a teacher and practitioner in our midst? There are others as old and older than he. It is for these and one other glorious reason and that is that during all this time he has dealt justly, loved mercy, and walked humbly in the sight of God."

These brief extracts were the burden of all the words of praise which came from the hearts of the loving pupils and friends of Elisha Hall Gregory. The occasion was one long to be remembered by all present.

#### NEBRASKA.

**Omaha Medical College** held its twenty-first annual commencement exercises, April 24, graduating a class of 38. Rev. E. H. Jenks, D.D., delivered the address to the class.

**Niobrara a Health Resort.**—Fort Niobrara is to be an established health resort for invalid soldiers of the army for the present. Only one company of infantry will be stationed at that post, the remaining portion of the quarters being given over to the medical department of the Department of the Missouri.

**Personal.**—Dr. J. H. Crabbs, Fremont, has opened an office at Leavitt.—Dr. Edward E. Fauver, Julian, has sold his property and practice to Dr. U. S. Yeager and will take post-graduate work in Chicago.—Dr. Ray H. Burrell, Ashland, has located in Lynch.—Dr. Edith Hayman Saunders has been appointed physician to the State Industrial School for Women at Milford.—Dr. J. R. Bullington, Nelson, has moved to Wilbur, Wash.

#### NEW YORK.

**Solarium for Saratoga Hospital.**—Mrs. Henry B. Hyde, New York City, has provided the Saratoga Hospital with a full equipment of sun parlors.

**Board of Health Organized.**—The newly-appointed Board of Health of Ilion has organized, with W. W. Gay as president and Dr. John H. Hunter as health officer and registrar.

**Hospital May Close.**—A special meeting of the board of managers of the Cortland Hospital Association was held, April 21, to consider the advisability of closing the institution, owing to the lack of financial support.

**Albany Hospital for Incurables** has received \$5000 from the John G. Myers estate, \$1000 from Miss Jermain, and \$6000 from other sources, all of which has been applied to the building fund. The management urges that further subscriptions be made, whereby the new building so much needed may be put up without delay.

#### New York City.

**Dr. Herman Biggs** has been appointed medical officer of the Board of Health at a salary of \$5000 a year.

**Engagement.**—Dr. Maxwell Benjamin announces his engagement to Miss Nettie Greenwood of New York City.

**Rainbow Cot Endowed.**—A service was held in the chapel in St. John's Hospital, Brooklyn, April 17, to present \$3000 for the endowment of the Rainbow cot in the children's ward.

**St. Mark's Hospital in Straits.**—It is reported that St. Mark's Hospital is in the hands of the sheriff, and that unless more funds are quickly forthcoming, the hospital must close its doors.

**Hospital Donations.**—By the will of Ernest von Pape, \$5000 is bequeathed to the German Hospital.—In response to appeals, nearly \$1600 has been subscribed to the Memorial Hospital for Women and Children, Brooklyn.

**A Woman Ambulance Surgeon.**—Dr. Emily Dunning, a graduate of the Cornell Medical College last year, has the distinction of being the first hospital interne here to do duty on an ambulance. She was appointed, after competitive examination, on the house staff of the Gouverneur Hospital, and the work as an interne will include a tour of duty on the hospital ambulance.

**Mount Sinai Hospital Needs Money.**—Appeals have been sent out by Isaac Wallach, president of Mount Sinai Hospital, in an effort to secure \$300,000 which is needed to complete its new hospital. The directors, by personal efforts, have obtained subscriptions to the building fund amounting to \$1,300,000, but the additional sum is still required to cover the entire cost of ground and construction.

**Automobile Ambulance Service.**—Several gifts of money have been made to Mount Sinai Hospital to establish and maintain an electric ambulance service. Murry Guggenheim, one of the directors, has given \$20,000, the income of which is to be the nucleus of a permanent fund to be used when the hospital moves into its new building. Henry R. Ickelheimer has given an ambulance to the hospital and Jefferson Seligman will pay for the maintenance of one so long as the hospital remains in its old quarters.

#### Buffalo.

**Dr. Lewis S. McMurtry**, Louisville, Ky., addressed the Section of Obstetrics and Gynecology of the Buffalo Academy of Medicine on "The Prophylaxis of Uterine Cancer Clinically Considered."

**Dinner to Dr. Bissell.**—A complimentary dinner was tendered Dr. William G. Bissell, at the Saturday Club, by the members of his class of practicing physicians to whom he has given a course in bacteriology.

**Personal.**—Dr. George Mills has been transferred as physician from the Manhattan State Hospital to the Buffalo State Hospital.—Dr. Jacob M. Kraus was appointed physician to the Erie County Penitentiary at a salary of \$600 per year.

**Law Regarding Coroners.**—By a recent act of the legislature the office of coroners for Erie County, with its associated office of postmortem examiners, has been abolished and a medical examiner at a salary of \$3000 and an assistant medical examiner at a salary of \$2000, who are to act in conjunction with the district attorney's office, have been instituted. Dr. Earl G. Danserth, late coroner, has been appointed medical examiner, and Dr. John D. Howland has been appointed assistant medical examiner by the Board of Supervisors.

**University of Buffalo Commencement.**—The Alumni Association of the University of Buffalo held its twenty-seventh annual meeting in Alumni Hall of the University Building, May 2. The classes of '52, '62, '72, '82 and '92 each held a class reunion. At the regular session of the association a symposium on "Gunshot Wounds" was presented, in which Major Louis A. La Garde, M.D., U. S. A., Lieut.-Col. G. Sterling Ryerson, M.D., R.A.M.S. South African Contingent, Toronto, Canada; Major William P. Kendall, M.D., U. S. A., Fort Porter, Buffalo; Roswell Park, professor of surgery, Buffalo, N. Y.; William Warren Potter, M.D., Buffalo; William C. Phelps, M.D., Buffalo; William H. Bergtold, professor of pathology, Denver, Col.; Herbert M. Hill, Ph.D., Buffalo, and Willis H. Mosher, Ph.D., Buffalo, N. Y., participated. The commencement exercises took place in Teck Theater, at 11 a. m. Rev. David J. Burrell, D.D., of Greater New York, delivered the address to the graduates.

## OHIO.

**Dr. J. S. Shaffer**, of the graduating class of the Miami Medical College, has just been appointed house physician at the Toledo State Hospital, at a salary of \$700 per year.

**Illegal Practitioner Fined.**—For practicing medicine in Lowellville without first having supplied himself with a certificate from the State Board of Medical Examiners, "Dr." Robert Erskine was fined \$20 and costs, April 21.

**Memorial to Dr. Kitchen.**—The Jackson County Medical Society, at a meeting held April 8, at Wellston, adopted resolutions expressive of the loss sustained by its members, his patients and society at large by the death of Dr. Benjamin F. Kitchen.

**New Doctors.**—Cincinnati College of Medicine and Surgery graduated a class of 20, on April 30. The college will then go out of existence because, as the officers claim, the rigidity of the preliminary qualification under the new law is so great that the school can not be conducted on a self-sustaining basis. The college was established in 1851.—Cleveland College of Physicians and Surgeons, Medical Department of Illinois Wesleyan University, holds its commencement exercises this evening, when a class of thirty will be graduated.—Ohio Medical University, Columbus, held its tenth annual commencement exercises, April 15. Dr. David N. Kinsman, Chancellor of the University, delivered the introductory address, after which Rev. John Henry Barrows, D.D., president of Oberlin College, discussed the practice of medicine from the Christian and humanitarian view-point. Dr. John Edward Brown then addressed the graduates on behalf of the faculty, after which Hon. Fred J. Heer, president of the board of trustees, conferred medical degrees on a class of 61.—Starling Medical College, Columbus, graduated a class of 32, April 10. Hon. P. W. Huntington, president of the Board of Trustees, conferred the degrees and delivered the address of the evening, and Dr. Starling Loving, dean of the faculty, spoke for the body.—The graduation exercises of the Toledo Medical College were held April 24. Ten students received diplomas from Judge D. R. Austin, president of the college; Dr. Edmund C. Brush delivered the address of the evening on "The Place and Work of the Medical Profession," and Dr. Park L. Myers addressed the graduating class on behalf of the faculty.

## TENNESSEE.

**Hamilton County Hospital.**—The County Court has made an appropriation of \$8600 for building an addition to the present county insane hospital at Chattanooga and for remodeling the old building.

**Dr. Happel's House Burned.**—Dr. T. J. Happel, Trenton, secretary of the State Board of Medical Examiners and president of the Board of Trustees of the American Medical Association, suffered loss by fire of his house and its contents, including valuable papers, April 22.

**Grant Medical Commencement.**—The Medical Department of Grant University, Chattanooga, held its graduating exercises, April 14. The graduating class consisted of 41. The diplomas were presented by President John H. Race. Dr. John R. Rathmell delivered the address to the graduating class, and the dean, Dr. Edward A. Cableight, announced the honors.

**Condemn Water Meter System.**—The Memphis and Shelby County Medical Society, at its meeting, April 15, passed the following resolutions by a unanimous vote:

*Resolved*, That it is the sense of this society that the free use of pure water is essential to the proper sanitation of any city, and especially so of Memphis, and that we condemn the meter system as it tends to check its full and necessary use.

*Resolved, further*, That the city council be respectfully solicited to oppose their introduction by the water company on any rate.

**Knoxville's New Hospital.**—The new City Hospital, Knoxville, erected at a cost of \$75,000 through the efforts of a few women of the city, was formally opened, April 14. The medical board is composed of the following physicians: Consulting—Drs. John M. Boyd, Michael Campbell, Chalmers Deaderick and John M. Kennedy; practice—Drs. Benjamin D. Bosworth, William R. Cochrane, William Delpuech, Charles P. McNabb and David H. Williams; surgery—Drs. Benjamin B. Cates, Thomas Ap. R. Jones, Henry J. Kelso, Samuel R. Miller and Walter S. Nash; gynecology—Drs. James M. Black, J. L. Garrard, Samuel M. Miller, and Robert P. Oppenheimer; obstetrics—Drs. Samuel L. Jones and William A. McCallie; eye, ear, nose and throat—Drs. Claudius M. Capps, Charles H. Davis, John H. Kinard and Benjamin F. Young; children—Drs. Howard L. Ijams and Ernest R. Zemp; dermatology—Drs. William S. Austin and James F. Scott, Jr.; pathology—Dr. William R. Lockett. The

board, at a recent meeting, elected Dr. John M. Boyd, chairman; Dr. Benjamin B. Cates, vice-chairman, and Dr. William R. Cochrane, secretary.

## GENERAL.

**Personal.**—Samuel H. Wainwright, M.D., medical missionary at Kobe, Japan, has returned to the United States to remain for one year and take a much-needed rest.

**Physician for Lepers Wanted.**—The Hawaiian Board of Health has removed Dr. Richard Oliver from his position as resident physician at the leper settlement on Molokai, on grounds of cruelty to a leper and serious neglect of duty. The board was unanimous in its action. The superintendent was also removed for neglect of duty in not preventing the cruelty mentioned. A physician is desired to fill the vacancy. The remuneration is \$250 a month.

**Vigorous Sanitation in Manila.**—The Board of Health of Manila is entering upon some of the details of sanitation in the outline previously mentioned in these columns. The native huts in some quarters, built on lowland tracts of great filth, are to be destroyed. To render the city of Manila immune to the plague all natives are being inoculated with Kitosato's serum. Cholera figures show in Manila 555 cases and 449 deaths, and in the provinces 1599 cases and 1169 deaths.

**No Yellow Fever in Havana.**—This encouraging report of Major Gorgas is very welcome to the contiguous coast of the United States, and is a great tribute to the efficient sanitation. The report says: "The number of deaths from contagious diseases has been exceedingly small; from typhoid fever, only 3; scarlet fever, 1; diphtheria, 1; smallpox, none. Not a case of the last-named disease has occurred since July, 1900. The prospect for escaping reinfection from yellow fever grows more and more hopeful as the months pass, and each month strengthens the claim that is made that this disease has been eradicated from Havana. At the end of February, five months had elapsed since the last case occurred, and when we consider that for a hundred years Havana has never been free from yellow fever for a single month, this claim seems very strong. We feel confident now that Havana will have no more yellow fever until it is introduced from some infected point outside of Cuba."

**Hygiene in Havana.**—The health officer of Havana, Major W. C. Gorgas, Surgeon U. S. A., had a sanitary census of the city taken, which shows the existence of 1187 cases of tuberculosis, according to the *British Medical Journal*. The patients have been urged to apply to dispensaries for relief, to sleep with bedroom windows open, to avoid confining occupations, and to take proper precautions relative to the disposal of the sputa. Special attention has been given to the cigar manufactories in this respect, particularly since tubercle bacilli were found in cigars which had been made by a consumptive. Cigar workers are now required, in finishing cigars, to moisten the tips with sponges, instead of with the lips, as was formerly done. The public reader—a peculiar institution common to all Cuban cigar factories—who is hired to read newspapers, novels, etc., to the hands while at work, will in future be required to devote a portion of his time to reading matter relating to elementary hygiene and the prevention of disease. The work is essentially educational and persuasive rather than coercive and is meeting with hearty support from the Cubans.

**The Association of American Medical Colleges** will meet in Saratoga, Monday, June 9, at 10 a. m. The morning program will be on educational subjects and open to visitors. The members of the Association of Southern Medical Colleges are invited to be present and take part in the discussion. The business session of the Association will be taken up at 3 p. m. of the same day. The educational program opens with the president's address, by Prof. Victor C. Vaughan. There follows a symposium on the amount of knowledge of French, German, Latin, mathematics, biologic sciences, physics and chemistry that should be demanded of applicants for admission to colleges of medicine. Among the speakers are Hon. James Russell Parsons, Jr., secy. Board of Regents, Univ. of N. Y.; and Drs. George M. Koher, Georgetown University; Robert Rayburn, dean of Howard University; W. H. Earles, Milwaukee Medical College; Joseph E. Smith, Woman's Medical College, Baltimore; John L. Hoffman, Syracuse Medical College; E. A. De Schweinitz, dean, Med. Dept., Columbian University; O. U. B. Wingate, Wisconsin Medical College; R. L. Whitehead, dean, Med. Dept., Univ. of N. C.; and G. W. Hubbard, dean, Meharry Medical College. Among the amendments proposed is one to strike out the provision for credit for time to graduates in dentistry, pharmacy or veterinary medicine.

**Smallpox.**

**Connecticut:** Citizens of Waterbury have requested that one of Montreal's medical health officers come to that city and settle a dispute concerning a disease which exists there. The city authorities are sending people to an isolation hospital, on the ground that they are suffering from smallpox. A number of French-Canadian citizens do not believe that the disease is smallpox at all, but only chicken-pox, and that view is supported by their doctors. Under those circumstances, they appealed to the Montreal Hygienic Committee for assistance. Dr. C. N. Valin accordingly left for Waterbury, April 23.

**Illinois:** The Chicago Department of Health reports that thirteen new cases of smallpox, one from Iowa, in the highly contagious stage, were discovered during the week and removed to the isolation hospital, from which eleven were discharged recovered, none died and forty-five remained under treatment at the close of the week. Since January 1 and up to April 26, inclusive, there have been 153 cases of the disease treated, 107 discharged recovered and one death. Not a single one of the 153 had ever been properly vaccinated. The most serious group developed among unvaccinated bridewell prisoners. Six cases developed among unvaccinated inmates of Zion college, one of the Dowie institutions. The lesson of Chicago's smallpox experience during the last three years amply confirms the tenets of the department's "Vaccination Creed": True vaccination always and surely protects against smallpox; nothing else does or can. Peoria County has agreed to pay one-third of the claim made against it by the city of Peoria, on account of smallpox, which amounts to \$21,000.

**Minnesota:** The smallpox report of the State Board of Health for the week ended April 14, shows a smaller number of new cases than have been reported for any previous week this year. The report shows 161 new cases, in 37 counties, and 51 localities, and no deaths. The previous week's report showed 205 new cases, in 40 counties, and 63 localities and 3 deaths. Minneapolis reports 12 new cases, and the only other locality in the state reporting more than 10 cases is St. Cloud, with 14 new cases. St. Paul reports 1 case. Smallpox bills for the care of non-resident patients, aggregating \$5,000, were passed on yesterday by the board and a report of the smallpox situation in the state since 1899 was presented. To April 14, 15,224 cases of smallpox, and 96 deaths from the disease were reported to the state board. In 1899 there were 257 cases, and 11 deaths; in 1900, 1371 cases, and 22 deaths; in 1901, 8485 cases, and 43 deaths, and in 1902, to April 14, 5111 cases, and 20 deaths.

**Montana:** Seven cases were reported in one family a few miles south of Billings, April 18.

**Pennsylvania:** In his annual report Director of Safety English of Philadelphia highly recommends an act of the legislature compelling vaccination and revaccination, a public record being kept of such vaccination, and providing that revaccination be required every five years or whenever the authorities may deem it necessary.

**South Dakota:** About 150 persons submitted to compulsory vaccination in the Buffalo Hump and Gold Mine saloons in Lead, at the hands of the County Board of Health, backed by the sheriff and several deputies, April 24. Cases of smallpox had been found in the saloons.

**Canada:** A second case of smallpox has been located among the students of Trinity Medical College, Toronto, and the college authorities are taking every precaution to see that there are no further cases. A report of the Civic Board of Health, of Montreal, shows that from last October to April of this year, 261 cases were admitted for treatment at the Hospital. Of this number 322 had never been vaccinated, 28 had been vaccinated many years ago, and bore poor marks, eight others had been vaccinated a good many years and bore good marks; while only three, or 1 per cent. of the whole, had been successfully vaccinated in seven years, and the marks in their cases showed that the vaccination had been done by amateurs, and unsatisfactorily.

**CANADA.**

**The Free Consumptive Hospital at Gravenhurst,** the gift to the National Sanitarium Association by Mr. W. J. Gage of Toronto, which will accommodate fifty patients, has been opened.

**Ontario Cancer Statistics for 1900.**—The total deaths recorded for this disease were 1055. There were 1041 and 975 in the two preceding years. The following gives the numbers for the past ten years, commencing with 1891: 579, 676, 678, 621, 620, 731, 927, 975, 1041, 1055. These figures show an increase of 100 per cent. between 1891 and 1900.

**The Ontario Birth Rate.**—According to the annual report of the Registrar General of the Province of Ontario which has just been handed to the profession, the total number of births recorded in 1900 were 46,127 as compared with 44,705 in 1899, showing an increase of 1422 and giving a rate of 19.8 on the estimated population of 1900, or 21.1 on the actual population of the census of March 31, 1901. This rate compares favorably with that of 1891, when with a population but 68,621 less, the total births were 46,754, or 21.1 per 1000.

**Closing Exercises at Bishop's, Montreal.**—The ceremonies in connection with the annual convocation of the medical and dental faculties of Bishop's College were held last week, Dr. F. W. Campbell, the dean of the medical faculty, submitted his annual report. This showed that the attendance at the college was the same as last year, the students being mostly drawn from the eastern provinces of the Dominion and the neighboring states. A building fund has been instituted during the year and it now amounts to \$2000. The valedictory of the medical faculty was delivered by Dr. D. K. H. Cowley.

**Personal.**—Dr. D. M. Anderson, house surgeon at the Toronto General Hospital and Dr. J. M. Jory of St. Catharines, Ont., have been appointed medical officers to the fourth Canadian contingent to South Africa. They sail from Halifax May 7. —Dr. H. A. Beatty, M.R.C.S., Toronto, has had a cable from the distinguished surgeon, Mr. A. H. Tubby, offering him the surgical registrarship of Westminster Hospital, London, England. Dr. Beatty, who has just returned home after spending four years abroad in post-graduate work, had lately been senior house surgeon to the Westminster Hospital. —Dr. J. E. Tremblay of Labrador is visiting the hospitals of Montreal.

**FOREIGN.**

**Japanese nurses,** in most cases, work but eight hours a day in private cases as well as in hospital work, according to the *Am. Jour. of Nursing*. The way nurses are overworked in this country is deserving of the attention of physicians.

**Campaign Against Charlatans in Germany.**—The Prussian authorities have prohibited the advertisement in railroad stations and like public places of charlatans and secret remedies, to take effect after present contracts have expired.

**Unna's prize** this year for the best work on the finer architecture of primary carcinoma of the skin—and the relations between proliferation of the epithelium and the resistance of the connective tissue, has been awarded to Drs. S. Beck and C. Krompecher, of Ofen-Pest.

**The Cinematograph Operation.**—Side shows in France are exhibiting the alleged cinematograph pictures of the operation on the Hindoo twins. Doyen writes to the French medical journals that the true films have never left his possession and have been exhibited only once. He has applied for legal injunction on the exhibitors in the side shows.

**The Battle of the Clubs.**—The physicians of Magdeburg have notified a large local sick insurance company that the 123 physicians on its list will retire and no others take their place, unless public retraction is made of an insulting speech delivered by one of the principal officers of the company at a public meeting. He is a well-known socialist and spoke very disparagingly of physicians in general.

**Municipal Sanitation.**—The German Public Health Association will hold its annual meeting in Munich, September 17 to 20. Among the matters to be considered are Supervision of Water Courses; Sanitation of Rural Districts; Influence of Quackery on the Health and Life of the Population; Damp Dwellings; Cause, Influence on Health and Measures for Amelioration; the Baking Trade from a Hygienic Point of View.

**Congress on Venereal Diseases.**—The second International Congress for the Prophylaxis of Syphilis and of Venereal Diseases will be held, as already announced, at Brussels, Sept. 1-6, 1902. Among the subjects for discussion are: What measures of public prophylaxis, under the form of legal provisions, should be taken against venereal diseases, specially with reference to the prostitution of minors, and with reference to procurers and bullies. The organization of measures of relief for sufferers. Contagion by wet nurses, midwives, arm-to-arm vaccination and instruments of labor. Penalties for transmission. Means of enlightening the youth and the general public on the social and individual dangers and on the methods of contagion. Basis for uniform statistics in all countries.

**Organization of the Profession in France.**—The "Association Générale des Médecins de France" was founded in 1858 for the purpose of assisting physicians in pecuniary distress, and has gradually assumed the functions of an insurance against

old age, disease and death. One of its features is that it guarantees to pay the premiums on the life insurance of its members when they are temporarily incapacitated from doing so. Brouardel has recently been elected president, and a bimonthly bulletin is to be issued to contain nothing but the news of the association. The premiums range from 12 to 96 francs a year. The latter sum entitles one to a pension of 1200 francs after 60 years of age, if commenced at 25. A premium of 54 francs insures against sickness, and entitles to a pension of 1200 francs in case of incurable illness. The association is making great efforts to induce young physicians to become members. The local associations are the branches of this general organization, which has now a capital of 2,473,066 francs, and disbursed last year 89,800 francs in pensions, etc.

**The German Surgical Congress**, held in Berlin on April 2-5, was well attended. After the president's address, the subject of "First Dressing of Wounds on the Battlefield" was opened by Professor von Bruns, of Tübingen. He prefers a paste for dressing bullet wounds as it will aid in the formation of a scab and will absorb the exudation. Bertelsmann of Hamburg and von Bergmann of Berlin said that bullet wounds often heal without suppuration. Others in the discussion showed sterile wound dressings ready for instant use on the field. Voelher of Heidelberg reported cases of fractures treated by suture, and recommended the procedure in cases where reposition of the fragments is difficult and where two bones are simultaneously broken. The "Etiology of Cancer" was the subject opened by Gussenbauer of Vienna. Although he was prepared to believe in the parasitic nature of carcinoma, no parasites had as yet been demonstrated in the growth which could be accepted as causal organisms. Von Kahldein of Freiburg held that recurrence was only possible when endothelial cells were left at the site of operation, or when the vascular system contained actual carcinoma cells. A cancer might exist in more than one location, and, after the removal of one focus, develop from another which had not before been recognized. Petersen of Heidelberg reinforced the above statement and regarded the giant cell as a protective cell which the organism used to kill off the cancer cells. Professor von Mikulicz of Breslau discussed 146 cases of carcinoma and sarcoma of the intestines. He considered that this form of new growth frequently remained latent for a longer period than others. In 83 cases not complicated by intestinal obstruction mortality was 30 per cent. after operation. He operated in two stages to prevent peritonitis. Hochenegg of Vienna reported 282 cases of carcinoma of the large intestine, 237 being rectal. In 25 per cent. lasting cure resulted from operation. Kronlein of Zurich discussed 264 operations he had made for gastric cancer and advised operation in all possible cases. Noske of Leipzig argued that every parasite failed of proof that it was either of usual occurrence or causal. Doyen of Paris and Schuller described certain parasites. Oscar Israel of Berlin denied that any parasite had aught to do with cancer, and the president humorously asked if any other gentleman happened to have any cancer parasites. Peritonitis and perityphlitis were considered by Korte of Berlin, Rehn of Frankfurt, Sprengel of Brunswick and others. Rehn urged that delay in operating when suppuration existed in the abdomen was dangerous, and that all deaths after operation are not due to the operation. Sonnenburg of Berlin discussed lung complications of appendicitis. In his experience pneumonia was uncommon, but emboli were frequent. He found no ground for blaming anesthesia or cold, but considered circulatory defects to blame. Bunge of Königsberg described his modification of Talma's operation for the relief of ascites. He sutures the omentum and other organs to each other and to the abdominal wall to lessen the pressure on the portal system. An instructive discussion on gastric ulcer followed. Kummel of Hamburg described the value of determining the freezing point of urine before operating on the kidney. When the freezing point rises above 0.6 C., it is not safe to operate. The normal is 0.56 C. One evening of the congress was devoted to lantern pictures. Among these were skiagraphs of anomalies of the patella by Joachimsthal of Berlin; a new instrument for examining for renal calculi by *x*-rays, shown by Shonberg of Hamburg; method of crippling the feet of Chinese women, shown by Perthes of Leipzig; cinematographic representations of operations by Doyen of Paris, including the severing of the Hindoo twins. These were very interesting and greatly enjoyed by the congress.

#### LONDON LETTER.

##### Hard Facts for the Antivaccinationists.

The number of cases in hospital is 1437 against 1567, 1526 and 1522 in the 3 preceding weeks; 274 new cases were ad-

mitted during the week, against 449, 389, 376 in the 3 preceding weeks. A most important analytical table of the deaths which have occurred from the epidemic has been issued by the Registrar-General and is a severe blow to the antivaccinationists. The deaths number 1015. Of these, excluding 66 cases in which vaccination or revaccination was not performed until after the patient's infection by smallpox, there was only one death within 10 years of the patient's vaccination. Moreover, this death occurred in an infant aged 13 months who was certified to have been imperfectly vaccinated. Of 457 deaths of persons vaccinated only in infancy not one occurred until the attainment of the tenth year and only 5 between 10 and 15. Of 398 deaths of unvaccinated persons 56 occurred under one year, 112 between 1 and 5 years, 58 between 5 and 10, 37 between 10 and 15. The table further shows that of persons under 20 years of age who were not protected by vaccination, 348 died of smallpox, while only 22 deaths occurred among those of the same age who were vaccinated in infancy. At ages over 20 there were 103 deaths of unvaccinated persons and 448 deaths of persons who had been vaccinated in infancy (including 13 who had been revaccinated only after infection).

#### The Investigation of Cancer.

The scheme for the investigation of cancer, to which we have previously referred in THE JOURNAL, is now taking definite shape. A fund of \$500,000 is to be raised to promote investigation into the causes, prevention and treatment of cancer. Steps will be taken to, 1. equip laboratories to be devoted exclusively to cancer research; 2. encourage researches on cancer within the United Kingdom or British dominions beyond the seas; 3. assist in the development of cancer research departments in various hospitals and institutions approved by the executive committee; 4. provide means for investigation in various other directions into the causes, prevention and treatment of cancer. Should the object of the fund be attained by the discovery of the cause and nature of cancer and of an effective method of treatment, the Royal Colleges, with the consent of the trustees, shall be empowered to utilize the fund either for equipping with the necessities for such treatment such hospitals as they may select or for forwarding research into other diseases. The fund will be administered by a president, vice-presidents, five trustees, honorary treasurer, general committee and executive committee. Of the first trustees three may be nominated by the donors of sums of \$5000 and one each by the Royal Colleges of Physicians and Surgeons. The general committee will consist of one member to be nominated by the local Government Board, one nominated by the colonial office, one nominated by the Royal Society, one nominated each by the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Faculty of Physicians and Surgeons of Glasgow, Royal College of Physicians of Ireland, and Royal College of Surgeons of Ireland, the Veterinary Colleges of London, Edinburgh and Dublin, and donors of sums of \$5000 and upwards. The executive committee may make contributions towards the development of the cancer research department of the Middlesex Hospital or a similar department of any other hospital if established. The working staff will consist of a general superintendent of the investigation, who may be the director of the central laboratory, assistants and other persons who may be appointed to make special investigations. There will also be a consulting staff consisting of persons skilled in scientific investigation, representatives of the various home and colonial government departments, physicians and surgeons attached to hospitals, statistical experts and others appointed by the executive committee.

#### Correspondence.

##### The Roentgen Rays in Detecting False and True Gems.

STERLING, ILL., April 21, 1902.

*To the Editor:*—About one year ago, in conjunction with a local jeweler, I exposed a number of gems, both real and imitation, to the *x*-rays. On developing the plate, we found that the image or shadow of the real gems was very dim and indistinct, while the shadow of the false gems was dark and very sharp, showing a well-marked difference in all instances: on carrying the experiments further we found that the shadows of all the stones we examined—and we examined all the more familiar ones—were invariably faint and indistinct, while the shadows of all the imitation ones were well marked and bold. We paid no particular attention to these experiments, as, while neither of us had ever seen any mention of this use of

the Roentgen rays, we thought that surely some persons had made this discovery before. But now after a year has elapsed and we have not seen any allusion to this method of determining the difference between true and imitation gems, I take the liberty of stating these facts to you, for if it is not known (which I can hardly believe), it is well worth bringing to attention, and if it is known it will do no harm to bring it into notice again.

Yours respectfully,

HARRY E. SMALL, M.D.

#### Brigadier-General George M. Sternberg.

PHILADELPHIA, April 24, 1902.

*To the Editor:*—Believing as I do that our Committee on National Legislation is engaged upon a most important work in behalf of the medical profession and the people of this country, it appears to me that every member of the American Medical Association should do whatever lies in his power to loyally uphold the hands of the committee and to assist it in attaining its objects. Acting entirely upon my own responsibility, I beg to respectfully suggest to my fellow members of the Association that an opportunity is afforded, at the present time, for displaying our full confidence in the committee and also of doing an act of justice to an ex-president, who is one of our most distinguished and honored colleagues, Brigadier-General George M. Sternberg, U. S. A. A bill has been submitted to Congress that will, if it passes, enable the President to appoint General Sternberg a major-general of the United States Army for the purpose of placing him upon the retired list. This bill has received the hearty endorsement of the Committee on National Legislation. To come to the immediate object of the present communication, I would ask each member of the Association, in all parts of the country, to at once communicate with the representatives from his district, or state, announcing the fact that this bill has the hearty support of the American Medical Association, and that its passage would be received as a marked act of favor to the profession and especially to the writer of the letter. As General Sternberg's time expires on June 8, the necessity of immediate action is evident.

Very truly yours,

FRANK WOODBURY.

218 South 16th St.

#### To Congressmen and Senators.

St. Louis, April 24, 1902.

*To the Editor:*—Copies of the following letter have been sent to our congressmen and senators. Very truly yours,

C. H. HUGHES, M.D.

St. Louis, April 19, 1902.

*My dear Sir:*—You would, I am sure, please the medical profession of the country by favoring a broad representative bill for a National Board of Health, representing the whole profession, as well as the Army, Navy and Marine-Hospital Service, with its chief eligible to a place in the President's cabinet.

The presidents of the Academy of Medicine and American Medical Association might be members, and one member might be nominated by the Senate and one by the House of Representatives for the people and states to make up the composition of the first board. One representative might come also from the American Association for the Advancement of Science. The present board scheme is too much and too exclusively Army, Navy and Marine. Very truly yours, C. H. HUGHES, M.D.

### Married.

WILLIAM A. DAVIS, M.D., to Mrs. Bertha Winter Davis, at Baltimore, April 9.

CARL G. SWENSON, M.D., to Miss Christine Johnston, both of Chicago, April 17.

WALTER A. RUSSELL, M.D., to Miss Mary H. Quinn, both of Providence, R. I., April 15.

HENRY A. KORNEMANN, M.D., to Miss Angeline Schulte, both of Newark, N. J., April 17.

WILLIAM G. DICE, M.D., Xenia, Ohio, to Miss Gertrude McClure of Toledo, Ohio, April 7.

J. T. SNIDER, M.D., Jewells, Ga., to Miss Della Graves Nisbet of Riverdale, Ga., April 10.

WILLIAM DOUGLASS, M.D., Macon, to Miss Mary Eleanor Johnson, at Charlottesville, Va., April 9.

JEREMIAH N. MARTIN, M.D., Mamaroneck, N. Y., to Miss Edyth Connery of New York City, April 12.

EUGENE B. SANGER, M.D., Surgeon-General of Maine, Bangor, to Miss Ethel Field, also of Bangor, April 16.

HERBERT R. DREWRY, M.D., Lambert's Point, Norfolk, Va., to Miss Annie B. Purnell of Raleigh, N. C., April 17.

THOMAS GREAR DUNLAP, M.D., Louisville, Ky., to Miss Ida Elizabeth Berd of Atlantic City, N. J., April 11.

GEORGE E. HIGARD, M.D., captain and assistant surgeon, I. N. G., to Miss Laura Ropiequet, both of Belleville, April 8.

EDWARD GARNETTE HANK, M.D., Tannerscreek, Va., to Miss Bessie Virginia Guy of Salem, Norfolk County, Va., April 16.

WILLIAM CHURCH GRISWOLD, M.D., formerly of Nassau, but at present an assistant surgeon in the Army, under orders to proceed to the Philippines, to Miss Helen Ruth Stout of Albany, N. Y., April 17.

### Deaths and Obituaries.

**Meredith Clymer, M.D.** University of Pennsylvania, 1837, died at his residence in New York City, April 20, aged 85. He was a grandson of George C. Meredith, one of the signers of the Declaration of Independence. After graduating in medicine he studied in Dublin, London and Paris, and then located in Philadelphia, where he was consulting physician-in-chief to the Cholera Hospital and professor of practice of medicine in the Hampden-Sidney Medical College, Richmond, Va. In 1851 he moved to New York, and was given the chair of practice in the University of the City of New York. At the outbreak of the Civil war he offered his services and was made surgeon of volunteers and later medical director of the Department of the South. In 1871 he was made professor of nervous and mental diseases in Albany Medical College. He was an accomplished teacher and writer. His contributions to medical literature were numerous, both in the way of original matter and as editor of various works. His latest original contribution appeared in 1874, on "The Legitimate Influence of Epilepsy Upon Criminal Responsibility." He was a member of the New York County Medical Society and twice served as president of the New York Neurological Society. He also served three terms as senior vice-president of the Alumni Association of the Medical Department of the University of Pennsylvania. He was associate editor of the *Journal of Nervous and Mental Disease* for a number of years.

**Theodore Walser, M.D.** Jefferson Medical College, Philadelphia, 1851, assistant sanitary superintendent of the Department of Health, Richmond Borough, died at his home in New Brighton, April 23, after an illness of three weeks, aged 77. Dr. Walser was the Nestor of the medical profession on Staten Island, having practiced there since 1857. He was a native of Germany. He held many public offices. In the early sixties he was deputy health officer of the port of New York. For many years he was health officer of the old village of New Brighton and held that position up to the time of consolidation. During the smallpox epidemic in New York years ago he volunteered his services to the state, and during the cholera scare he did good service on Hoffman and Swinburne islands. Dr. Walser was one of the founders of the Smith Infirmary.

**Cephas L. Bard, M.D.** Jefferson Medical College, Philadelphia, 1866, the first American physician to locate in Ventura, Cal., a member of the American Medical Association, a member and some-time president of the Southern California Medical Society and of the Medical Society of the State of California, and one of the most prominent men of Southern California, died at the Elizabeth Bard Memorial Hospital, Ventura, April 20, from malignant disease, aged 59. The hospital in which he died was established by his brother, United States Senator Bard, and himself, in memory of their mother, and his death was the first to be noted on the hospital records.

**Julius Wise, M.D.** University of Michigan, Ann Arbor, 1872, formerly city physician of Cincinnati, who during the yellow fever epidemic in Memphis in 1878 had charge of the quarantine camps, and did noble volunteer work, as a result of which his health became so impaired that he was unable to resume practice, died at the Baptist Hospital, Chicago, April 19, after a short illness, aged 51.

**Franklin B. Tuttle, M.D.** Yale University, New Haven, 1863, for nearly forty years a practitioner of Naugatuck, Conn., some-time president of the New Haven County Medical Association and of the Naugatuck Medical Association, and member of the legislature, died at his home in Naugatuck, April 21, from neuralgia of the heart, aged 60.

**Charles Wirgman, M.D.** Jefferson Medical College, Philadelphia, 1877, a well-known physician of Philadelphia, a trustee of Jefferson Medical College and visiting physician at the Children's Howard and Orthopedic hospitals, died at his residence, April 19, after a long illness, aged 55.

**D. R. Walker, M.D.** Medical College of Indiana, Indianapolis, 1873, died, April 16, from congestion of the brain and stomach, at his home in Reese Mill, Boone County, Ind. He had never fully recovered from a stroke of paralysis in St. Augustine, Fla., in January last.

**Alexander H. Henderson, M.D.** University of Nashville, 1873, prominent as a physician in Starke County, Ind., who had represented that county at every Republican State Convention since 1872, died suddenly at his home in Knox, April 21.

**George F. Hulbert, M.D.** Washington University, St. Louis, 1886, a prominent physician of St. Louis, formerly in the United States Marine-Hospital service, died at St. John's Hospital, St. Louis, after a prolonged illness, April 22, aged 47.

**James E. McDavitt, M.D.** Washington University, St. Louis, 1855, one of the oldest practitioners of Western Illinois, died suddenly at his home in Quincy, from uremic coma, April 22, aged 75. He retired from active practice in 1898.

**Henry Allen, M.D.** Rush Medical College, Chicago, 1865, one of the earliest settlers on the Otter Reserve, who had practiced medicine in Nebraska from that time until 1892, died at his home in Odell, April 16, aged 78.

**Harry P. Hinchliffe, M.D.** University of Pennsylvania, Philadelphia, 1894, a popular physician of Elkton, Md., died, April 19, two days after an operation for appendicitis, at his home in Elkton, aged 30.

**Nathaniel M. Freeman, M.D.** Yale University, New Haven, Conn., 1852, a wealthy retired physician of New York City, died suddenly from heart disease at the Aschenbroedel Club, in that city, April 18, aged 81.

**Yancey L. Poole, M.D.** Atlanta (Ga.) Medical College, 1889, an esteemed practitioner of Union County, S. C., died from appendicitis at his home in Union, April 21, after a short illness, aged 35.

**Edward A. Maris, M.D.** University of Maryland, Baltimore, 1841, a venerable and prominent practitioner of Baltimore, died at his home in that city, April 20, after an illness of two weeks, aged 81.

**E. Harold Williams, M.D.** College of Physicians and Surgeons, Baltimore, Md., 1888, died at his home in Hamilton, Ga., April 19, from consumption, after an illness of one year.

**Abram Harshberger, M.D.** University of Pennsylvania, Philadelphia, 1868, a native of Zion, Centre County, Pa., died suddenly at his home in Philadelphia, April 10, aged 62.

**William H. Masterson, M.D.** Detroit College of Medicine, 1893, a colored physician of Madisonville, Ky., died in his office in Madisonville, Ky., April 21, after a short illness.

**William H. Keyes, M.D.** University of Michigan, 1879, died suddenly at West Bay City, Mich., from heart disease.

**Edwin A. McArthur, M.D.**, died at his home in Columbus, Ohio, from blood poisoning, April 14.

## Association News.

### Railroad Rates for Saratoga Meeting.

The Committee on Transportation has been making every endeavor to secure a railroad rate of one fare for the round trip with a thirty-day time extension, but has been unable to have the railroads grant the request. The Trunk Line Association, which in this instance under railroad regulations has the deciding of the matter of rates, etc., has finally decided to grant a rate of a fare and a third on the certificate plan, with an extension time limit to July 2, and make a fifty-cent charge on all tickets extended beyond June 16, that is to say, those beginning their return journey not later than June 16 will not be charged the fifty-cent fee extra, but in all cases where the return trip

is begun after June 16, and on or before July 2, a fifty-cent fee will be charged. In purchasing tickets to this meeting it is necessary to secure at the time the ticket is purchased a certificate entitling the holder to the reduction on the return ticket. All certificates must be presented to Dr. William E. Swan at Saratoga for his visé and the stamp of the railroad agent detailed at the meeting, on either June 11, 12 or 13, before presentation to the local ticket agent for the reduced rate returning. Those who desire the time extension beyond June 16, in addition to having their certificates viséd and stamped as herein directed, must also deposit their certificates with the railroad agent and make application for the desired extension, paying the fifty-cent fee. The trunk lines have agreed to extend the rate to the American Academy of Medicine which meets at Saratoga, June 7 to 9, and accept the visé of Dr. Swan on their certificates, as herein indicated, and the same time extension will be granted that society, therefore tickets to either meeting will be on sale in the Trunk Line Territory for the going trip from June 4 to June 12 or 13. At this writing none of the other passenger associations have concurred in this rate except the New England Railroad Association and the Central Passenger Association. It is expected, however, that the other associations will eventually agree to the rates and terms of the trunk lines and will sell tickets in their territory at a date early enough to permit arrival at Saratoga three days before the opening of the combined meetings. Later information in the matter of rates will appear regularly in THE JOURNAL.

H. L. E. JOHNSON, M.D.,

Chairman Committee on Transportation.

### Special Report of the Committee on National Legislation.

The following communication has been sent to the delegates who attended the third annual conference of this committee and to the secretaries of the medical societies of the several states and territories. All members of the American Medical Association are requested to assist this committee in their efforts to secure favorable action by Congress on the various matters mentioned:

The Third Annual Conference of the Committee on National Legislation, held at Washington, D. C., April 10-11, decided to publish in THE JOURNAL of the American Medical Association, a synopsis of its work, and each delegate was requested to present the same to his society at the earliest opportunity. Please refer to THE JOURNAL of April 19, pp. 1023-25 for said report, to which I hereto add the special recommendations for the U. S. Navy which were approved by the conference, but which by error do not appear in the synopsis published, viz.: S. Bill 4112, providing for an increase in the medical corps of the navy; H. R. Bill 8194, equalizing the pay of officers of the line, medical corps, pay and chaplain corps of the navy with officers of corresponding rank in the army and marine corps; the bill providing for a navy hospital at Annapolis, and the bill increasing the naval hospital corps. Your attention and that of your society is especially called to the bill proposed by the conference, which promotes and honors Surgeon-General Sternberg, Ex-President of the American Medical Association, known as S. 5213, and H. R. 13725, the Gallinger-Grosvenor Bill, providing for the selection and retirement of medical officers in the army. The Committee on National Legislation hereby requests each member of your society to write immediately to his own senator and representative, and also to Senator Gallinger and Congressman Grosvenor, urging the immediate passage of S. Bill 5213 and H. R. Bill 13725.

Very truly yours,

[Signed]

H. L. E. JOHNSON, M.D., Chairman.

## Societies.

### COMING MEETINGS.

American Medical Association, Saratoga Springs, N. Y., June 10 to 13.

Nebraska State Medical Society, Omaha, May 6-8, 1902.

Texas State Medical Association, Dallas, May 6-9, 1902.

Kansas Medical Society, Lawrence, May 7-9, 1902.

American Therapeutic Society, New York City, May 13, 1902.

Utah State Medical Society, Salt Lake City, May 13-14, 1902.

Oklahoma Territory Medical Association, Oklahoma City, May 14, 1902.

Arkansas Medical Society, Little Rock, May 13-15, 1902.

New Hampshire Medical Society, Concord, May 15-16, 1902.

Illinois State Medical Society, Quincy, May 20-22, 1902.

American Surgical Association, Albany, N. Y., June 3-5, 1902.  
 Medical Association of the State of Missouri, St. Joseph, May 20-22, 1902.  
 Kentucky State Medical Society, Paducah, May 7-9, 1902.  
 Arizona Medical Association, Tucson, May 21-22, 1902.  
 Medical Society of West Virginia, Parkersburg, May 21-23, 1902.  
 Medical Association of Montana, Anaconda, May 21-22, 1902.  
 Iowa State Medical Society, Des Moines, May 21-23, 1902.  
 Indiana State Medical Society, Evansville, May 22-23, 1902.  
 American Pediatric Society, Boston, May 26-28, 1902.  
 American Laryngological Association, Boston, Mass., May 26-24 1902.  
 American Gynecological Society, Atlantic City, May 27, 1902.  
 Connecticut Medical Society, New Haven, May 28-29, 1902.  
 Ohio State Medical Society, Toledo, May 28-30, 1902.  
 American Laryngological, Rhinological and Otolological Society, Washington, D. C., June 2-4, 1902.  
 Louisiana State Medical Society, Shreveport, June 3-5, 1902.  
 Medical Society of the State of North Carolina, Wilmington, June 3-7, 1902.  
 Maine Medical Association, Portland, June 4-6, 1902.  
 Wisconsin State Medical Society, Milwaukee, June 4-6, 1902.  
 Rhode Island Medical Society, Providence, June 5, 1902.  
 South Dakota State Medical Society, Scotland, June 4-5, 1902.  
 Association of Military Surgeons of the United States, Washington, D. C., June 5-7, 1902.  
 American Orthopedic Association, Philadelphia, Pa., June 5-7, 1902.  
 American Academy of Medicine, Saratoga Springs, N. Y., June 7, 1902.  
 American Association of Life Insurance Examining Surgeons, Saratoga Springs, June 9, 1902.  
 National Confederation State Medical Examining and Licensing Boards, Saratoga Springs, N. Y., June 9, 1902.  
 Association of American Medical Colleges, Saratoga Springs, N. Y., June 9, 1902.  
 American Climatological Association, Los Angeles, Cal., June 9-11, 1902.  
 American Proctological Association, Saratoga Springs, N. Y., June 10, 1902.  
 Medical Society of Delaware, Newark, June 10, 1902.  
 Massachusetts Medical Society, Boston, Mass., June 10-11, 1902.  
 Colorado State Medical Society, Pueblo, June 17, 1902.  
 American Medico-Psychological Association, Montreal, June 17-20, 1902.  
 Minnesota State Medical Society, Minneapolis, June 18, 1902.  
 Medical Society of New Jersey, Atlantic City, June 24-26, 1902.  
 Washington State Medical Society, Tacoma, June 24-26, 1902.  
 Michigan State Medical Society, Port Huron, June 26-27, 1902.

**Kankakee Valley District Medical Society.**—This Society will meet at Knox, Ind., May 6.

**Plains (Texas) Clinical Society.**—This Society, which was organized at Amarillo, in January, with a membership of 16, held its regular monthly meeting at Amarillo, April 9. It now has a membership of 23.

**American Climatological Association.**—The nineteenth annual meeting of this Association will be held in Los Angeles, Cal., June 9-11, at the Westminster Hotel, under the presidency of Dr. Samuel A. Fisk, Denver.

**Carbon County (Pa.) Medical Society.**—At the annual meeting of this Society, at Manch Chunk, Dr. P. D. Keiser, New Mahoning, was elected president; Dr. David R. Davis, Lansford, vice-president, and Dr. James B. Tweedle, Weatherly, secretary and treasurer.

**Ohio State Pediatric Society.**—This Society, which holds its next annual meeting on May 27 and 28 at Toledo, announces that in addition to the regular program a special address will be given by Dr. F. X. Dereum, Philadelphia, on "Mental Disorders of Children."

**Boone County (Ark.) Medical Society.**—At the annual meeting of this Society, held in Harrison, April 8, Dr. Charles L. Burns, Harrison, was elected president; Dr. James R. Potts, Bellefonte, vice-president; Dr. Hugh L. Routh, Batavia, treasurer, and Dr. Ezra L. Evans, Harrison, secretary.

**Tarrant County (Texas) Medical Association.**—The physicians of Fort Worth met on April 14 and organized a county medical society, with the following officers: Dr. James T. Feild, president; Drs. James L. Cooper, Robert B. Grammer and Charles P. Brewer, vice-presidents, and Dr. Barber, secretary and treasurer, all of Fort Worth.

**Hartford County (Conn.) Medical Society.**—The one-hundred-and-tenth annual meeting of this Society was held at Hartford, April 16. Dr. Nathan Mayer, Hartford, was elected president; Dr. Howard O. Allen, Broadbrook, vice-president; Dr. William G. Craig, Hartford, clerk; Dr. Walter R. Steiner, Hartford, county reporter, and Drs. Philo W. Street, Suffield, Charles D. Alton, Hartford, and Joseph A. Kilbourn, Hartford, were elected censors.

**Hampden District (Mass.) Medical Society.**—This Society held its annual meeting and banquet at Springfield, April 15. The following officers were elected: Dr. Stephen A. Mahoney, Holyoke, president; Dr. James W. Hannum, Ludlow, vice-

president; Dr. Harry C. Martin, Springfield, secretary and treasurer; Drs. George L. Woods, Springfield, Carl A. Allen, Holyoke, Harvey W. Van Allen, Springfield, Robert P. M. Ames, Springfield, and Daniel E. Keefe, Springfield, censors, and Dr. J. Philip Schneider, Palmer, commissioner of trials.

**Pennsylvania Society for the Prevention of Tuberculosis.**—The annual meeting of this Society was held in Philadelphia, April 9. Requests received from various parts of this country and Canada for information show an increasing interest in the subject. Dr. Guy Hinsdale, after three years of service as president, declined re-election, and Dr. Howard S. Anders was elected. The laity has a good representation in the management of the Society. Among the vice-presidents are Drs. J. Solis-Cohen, Benjamin Lee, S. A. Knopf, William Moss, Samuel G. Dixon, and Lawrence F. Fliek. The secretary is Dr. Alexander H. Davisson.

**Mississippi Valley Medical Association.**—The Chairman of the Committee of Arrangements for the twenty-eighth annual meeting of this Association, Dr. A. H. Cordier, Kansas City, has announced the dates of the next meeting in Kansas City as October 15 to 17. The president, Dr. S. P. Collings, Hot Springs, Ark., has announced the orators for the meeting: Dr. C. B. Parker, Cleveland, to deliver the address in surgery and Dr. Hugh T. Patrick, Chicago, the address in medicine. A cordial invitation is extended every physician in the United States, but especially of the Valley, to attend this meeting and take part in its proceedings. Titles of papers should be sent the secretary, Dr. Henry Enos Tuley, 111 W. Kentucky Street, Louisville, Ky., at as early a date as possible.

**New Mexico Medical Society.**—The twenty-first annual session of this Society was held at Albuquerque, April 16. The meeting was called to order by President Dr. George W. Harrison, Albuquerque, and the hospitality of the city was offered to the members by Mayor Charles F. Myers. Dr. James H. Wroth welcomed the visitors on behalf of the profession of Albuquerque, and Dr. William R. Tipton, Las Vegas, responded for the Society. The president's address was on "Medical Organization." Among the most important papers presented was one by Dr. George C. Bryan, Alamogordo, president of the Territorial Board of Health on "Licensure of Physicians in New Mexico." This evoked extended discussion and a resolution was finally adopted recommending that the Territorial Board of Health prepare a list of medical colleges whose graduates would be accepted without re-examination. The election of officers resulted as follows: Dr. Walter G. Hope, Albuquerque, president; Drs. George C. Bryan, Alamogordo, Thomas P. Martin, Taos, and Edwin B. Shaw, East Las Vegas, vice-presidents; Dr. J. Frank McConnell, Las Cruces, secretary, and Dr. George W. Harrison, Albuquerque, treasurer. The Bernalillo County Medical Society entertained the members at a banquet in the evening.

### TRI-STATE MEDICAL SOCIETY (IOWA, ILLINOIS AND MISSOURI).

*Proceedings of the Tenth Annual Meeting, held in Chicago, April 3 and 4, 1902.*

*(Concluded from p. 1103.)*

The Society convened at the Great Northern Hotel, under the Presidency of Dr. John C. Murphy of St. Louis, Mo.

#### Acute Delirium.

DR. FRANK P. NORBURY, Jacksonville, Ill., read this paper and said that acute delirium is an etiologic problem upon which the leading authorities do not agree. It may not be regarded as an entity, but a combination of pathologic conditions, chief of which is an encephalitis more or less intense and almost invariably fatal. The tendency is of late to regard the disease as an infection, but as yet no pathogenic bacteria family group have been isolated. The Russian school, following the lead of the Italians, have made reports, conclusive in their deductions, endorsing the infection theory. From a clinical study of three cases, one of which came to autopsy, Dr. Norbury endorses the infection theory, and says the disease is comparable in its clinical history to other of the severe infections. The question of differential diagnosis is aided by laboratory methods.

#### Diagnosis of Cancer of the Breast.

DR. ALFRED ROULET, St. Louis, Mo., read a paper with this

tit'e. He said there is no doubt that in its early stages every cancer of the breast is a strictly localized condition and that its successful treatment depends entirely upon early diagnosis and immediate radical extirpation of the malignant focus. In advanced cases the diagnosis is easily made, but in the early stages it is often exceedingly difficult to distinguish cancer from abscess, syphilis, tuberculosis, sarcoma, cysts and the benign tumors. Text-book distinctions do not hold in practice. The diagnosis can only be made after most thorough physical examination and a searching investigation of the history.

#### Multiple Neuritis.

DR. DANIEL R. BROWER, Chicago, said, in a paper on this subject, that the diagnosis of multiple neuritis in its classical form was very simple, but at the bedside there were few classical cases, so that errors in diagnosis were frequent. As the prognosis of multiple neuritis is usually favorable under proper treatment and the prognosis of the diseases with which it was usually confounded is very bad, a correct diagnosis is of great importance. The principal poisons producing a multiple peripheral neuritis are alcohol, lead, arsenic and the toxins of the various micro-organisms, especially those that produce diphtheria, influenza, typhoid fever, gonorrhea, syphilis, leprosy, and beri-beri.

In the typical cases of multiple neuritis there is symmetrical localization of motor, sensory and vasomotor symptoms. In the earlier stages the symptoms are the result of irritation of the nerve; while the later symptoms are those of destruction. In the beginning there are muscular cramps and spasms, shooting pains and paresthesia. Later on, paralysis and anesthesia.

The diagnosis of alcoholic neuritis was based upon the evidences of chronic alcoholic poisoning, found in the digestive, circulatory and nervous systems. The onset was usually insidious, weeks or months being necessary for its full development. The earlier symptoms were numbness, tingling, muscular cramps, tremors and vasomotor disturbances, such as cold or clammy hands or feet, or a hot and burning sensation in the same extremities. In a few cases there was marked psychic disturbance.

Arsenical neuritis greatly resembles alcoholic neuritis. The differentiation from alcoholic neuritis was made in the few cases he had seen by the absence of any evidences of alcoholism, by the edema of the eyelids, pigmentation, epigastric pain and nausea. These cases were the result of the continued use of large doses of Fowler's solution and the tremors were more marked than in alcoholic neuritis. The knee-jerks and typical reflexes were present. Some cases were the result of the combined action of alcohol and arsenic, as evidenced by the remarkable epidemic that occurred in Manchester, England, in 1900, from beer. The source of arsenic was traced to sugar used in brewing. Recent investigation by Ross would seem to indicate that arsenic may be the principal etiologic factor, although hitherto it has been regarded as microbic.

The treatment of the several forms of neuritis has in common, rest, the relief of pain and insomnia; also the use, in the early stages, of the constant galvanic current of low amperage, applied daily to the nerve trunks involved, and attention to elimination by skin, bowels and kidneys. The alcoholic patients require the bromids, with codein in such doses as necessary to secure a reasonable degree of comfort, and the use of nerve tonics, of which strychnia is the most serviceable. In alcoholic neuritis it is very essential to withdraw at once and entirely alcoholic stimulants. In the treatment of beri-beri, it is the opinion of physicians who had had much experience with the disease that the patient must be moved from the locality where the disease was contracted, must have absolute rest in bed, mild laxatives, diuretics, tonics and anodynes. When cardiac failure seemed imminent, strychnia and nitroglycerin give the best results. After the acute stage of the several forms of multiple neuritis has passed, the patients require vigorous restorative treatment.

The diet throughout must be carefully regulated to suit the digestive condition of the patient. As soon as the acute pain has disappeared, the use of the galvanic current of a proper amperage, interrupted so as to produce muscular con-

traction, is indicated. The séances should be short; not more than three or four contractions of each group of muscles by a current of the least possible amperage should be made daily. Gentle massage should be commenced at the same time and the severity of this treatment should be increased as muscular soreness subsided. This exercise of the atrophied muscles will ordinarily result in their slow development and after a time they will respond to the Faradic current, which should then be substituted. Much benefit may be had by the hypodermic use of strychnia daily, beginning with 1/60 and gradually increasing it to a full physiologic dose. If the case did not yield, hypodermic injections of the chlorid of gold and sodium, gr. 1/24, may be added to the daily treatment. As soon as possible the patient should be encouraged to make frequent voluntary muscular movements. Many cases of multiple neuritis in the beginning of treatment are discouraging and the physician is apt to consider them hopeless too soon. Some of the most satisfactory results that the writer had obtained were in cases of long-standing neuritis which had been abandoned by physicians as incurable.

#### Intemperance and Life Insurance.

DR. C. F. WAHRER, Fort Madison, Iowa, contributed a paper with this title. The author holds, despite many conflicting opinions on the use of alcohol, that two things are certain: all scientists agree that even its moderate use is not beneficial and may easily be harmful, and that all insurance companies regard drinkers as belonging to the class of hazardous risks. Drinkers easily fall victims to such diseases as nephritis, heart disease, pneumonia, typhoid fever and cirrhosis of the liver, and since intemperance is most frequently found among the lewd and vicious, they are particularly liable to gonorrhea and syphilis. Once attacked, their chances for recovery are greatly lessened by the life they have led. Men following hazardous occupations are liable to injuries and, if intemperate, they stand operations poorly and their chances for recovery are relatively small.

Since intemperance plays such an important rôle in life insurance, it is well to note the fact that the children of drinkers are poorer risks than those whose ancestors led pure and temperate lives. There are two kinds of risks, the standard, embracing those who pass a satisfactory examination and receive an unmodified policy at usual rates; and the sub-standard, who, on account of an unsatisfactory examination, are given a modified policy.

The author suggests the establishment of a new class, the super-standard class, in which, beside possessing the good qualifications of the standard risk, the applicant must be a teetotaler. He thinks it just that these should not pay for the shortcomings of others and that there is a sufficient number of them to justify the creation of a separate class to whom policies should be issued at reduced rates.

#### Treatment of Malignant Tumors by the X-Ray.

DR. WILLIAM ALLEN PUSEY, Chicago, read a paper on this subject, illustrated by stereopticon.

#### Medical Education.

This was the subject of the president's address by Dr. John C. Murphy, St. Louis, Mo. A man who aspires to teach others should himself have a thorough understanding of what he attempts to teach and should be chosen on account of his special knowledge of some particular subject, and not on account of his ability to buy stock in the college. It is only by concentration in some particular channel that one can hope to become a peer among his fellows and rise above mediocrity. The medical teacher should have a proper preliminary training. No man can hope to turn out a finished product unless he himself is finished. The professor of medicine is not preparing his pupil to become a mere artisan; he is fitting him for the noblest work of mankind: to alleviate human suffering, to be the mediator between life and death. He is God's architect, who gives him the solid ground of man's intellect, to erect thereon a monument that will endure for all time, for good or evil. Great responsibility rests upon the medical educator. If his work is well done, as he approaches the end of his

career and takes a retrospective glance down the vista of his life, he sees here and there young intellectual giants of his own creation, ready to continue the work he has so well begun, to perpetuate his name, and enjoy and transmit the heritage of his genius.

The medical student is the very center of the arch; the keystone of the structure, without which all must fall. This age abounds with many opportunities for the earnest worker along the various avenues of science, but there are none which offer greater opportunities for renown than the science of the saving of human life. Men should be famous for the good they do to others. There are more heroes in the medical profession than in all the armies of the world; men who every day risk their lives amidst scenes of pestilence and disease that others may live. The man who goes forth to wage war on disease is a greater hero than Alexander the Great or Julius Cæsar.

He would say to the prospective medical student: "Let him think well of what he is about to undertake; before he begins to dissect others, let him, metaphorically, dissect himself, and see if he possesses the moral and intellectual attributes necessary to success."

"The world of the microscope alone is only half explored, and holds many secrets for future generations to unfold. If there are to be other Virchows, other Senns, other Kellys and other Oslers to take their places when they are gone, it remains for the medical colleges of to-day to furnish the material out of which they are to be evolved. The whole future of medicine and surgery for centuries to come depends on the medical educators of to-day. The training of a doctor is like the training of an infant, it must begin with his ancestors, in order to be successful. The parent from whom he comes must be healthy in mind and body if the offspring will be likewise. The course of four years in college is to the student what the period of prenatal existence is to the infant, a time of development and preparation for an independent life. What does the term *alma mater* signify but loving mother? If we would have our children do us credit, we must have a care as to the kind of material we select for their making. We must not be like the fishermen who let down their drag-nets and gather in all that are caught in their meshes. Unfortunately, too many colleges pursue this method, and cast their nets in the form of enticing literature to tempt the smith from his forge and the husbandman from his plow, where nature intended them to remain. They come, they see, but they conquer not. Their cherished hopes are blasted; their desires unsatisfied; their time wasted. All they have to show for their endeavors is a worthless piece of parchment bestowing a worthless title. The great percentage of them must go back to the forge and the plow or starve." Dr. Murphy referred to a college commencement where 214 students were graduated with the degree of M.D. There had been no failures. He did not believe that such a number of men gathered in from the highways and byways could successfully pass an examination of any severity. What is the secret? It is the commercialism which has crept into the medical colleges. Graduates are turned out who have no ability themselves and they become mere drummers for the college professors. The more half-educated men graduated, the better it is for Professor Laparotomy and the other distinguished specialists. If the graduates were well educated gentlemen, it might work a hardship on the professors' bank accounts, but what a boon it would be to the eighty millions of unsuspecting public! When all medical colleges become departments in endowed universities and the professors are paid for their services, the sooner will commercialism be eliminated and we will soon have fewer colleges and better doctors. And the medical profession will not be long in again establishing itself upon the high pedestal of honor it once occupied. The march of disease will be stayed and as a people we will become as were the ancient Greeks, marvels of beauty and powers of moral, intellectual and physical strength; and we as physicians will have the welfare of a grand and glorious nation in our keeping.

#### Cataract Operation in the Very Old.

DR. A. B. HALE, Chicago, read a paper on this subject. He spoke of trying to overcome the prejudice among the laity

against cataract operation in the very old. The eye is more amenable to surgical interference in these cases than other organs of the body. He reported six cases of operation in patients aged 80 to 100 years and makes the following conclusions: 1. Tissues in the old are apt to be friable and the cataract over-ripe. 2. Vision need not necessarily be impaired. 3. Patients stand the operation surprisingly well and with little reaction. 4. Every case of cataract in the very old, if the retina and nerve seem to functionate well, should be given the chance of operation. 5. Emergencies should be anticipated and met at once. 6. Repair proceeds slowly, but as securely as at an earlier age.

#### Splanchnoptosis.

DR. FRED BYRON ROBINSON, Chicago, made a few remarks on this subject, which were illustrated by charts.

#### Tetanilla.

DR. J. W. HANNA, Winfield, Iowa, detailed a case of tetanilla. This name was applied to a peculiar neurosis characterized principally by paroxysmal tonic convulsions of certain groups of muscles. The disease attacks by preference children and young adults, varying in age from fifteen to thirty.

#### The Hygiene of the Pregnant and Puerperal States.

DR. C. E. PADDOCK, Chicago, read this paper and emphasized these points: Pregnancy borders so closely upon a pathologic condition that a physician's advice is necessary. Careful examination of the urine must be made frequently, and at least once a month a twenty-four-hour specimen is to be had. The prophylactic treatment of eclampsia lies in strict attention to this, and also in the use of the daily bath. The physician who carries out a systematic treatment of his cases has fewer mortalities and fewer conditions of morbidity.

DR. FLORENCE PATRICK, Burlington, Iowa, followed with a paper in which she covered essentially the same ground as that outlined in the paper of Dr. Paddock.

#### Infections of the Puerperal State and Their Surgical Treatment.

DR. EMORY LANPHEAR, St. Louis, Mo., the author of this paper, said that the fatality from puerperal infection attended by midwives was appalling. The mortality arose from several things, first, non-familiarity with the various causes of puerperal infection; second, inappreciation of asepsis; third, gross carelessness; fourth, meddlesome interference with natural processes; fifth, the spread of venereal diseases.

#### The Pathologic Status of Retroverted Uteri.

DR. WILLIAM A. TICHENOR, Chicago, read a paper on this subject. The author thinks there are certain grave pathologic conditions found in the uterus and adnexæ in which the first step is backward displacement. Among the more grave is prolapsus. Practically, all cases of prolapsed uteri are first displaced backward, for it is practically impossible for a uterus to slide down the vaginal canal if the cervix is well back toward the sacrum and the fundus well up against the pubes. In this position the organ lies across the axis of the vaginal outlet, and will not prolapse; but when the fundus is in the hollow of the sacrum the organ is in the most favorable position for gravitating toward the vaginal outlet. The retroverted position militates against the expulsion of menstrual and other secretions. This position retards venous circulation, thereby favoring the growth of any pathogenic bacteria that may find lodgment. It lessens the woman's ability to bear children by decreasing the chances of conception and increasing the chances of abortion. He thought about one-third of all gravid uteri abort. The retrodisplaced uterus is a prominent etiologic factor in prolapsed ovaries. Retroverted uteri and prolapsed ovaries are in the most favorable position to be irritated and injured by the passage of hard feces, and during the act of coitus.

#### Officers for the Ensuing Year.

The following officers were elected: President, Dr. Alexander Hugh Ferguson, Chicago; First Vice-President, Dr. Flavel B. Tiffany, Kansas City, Mo.; Second Vice-President, Dr. J. C. Sullivan, Cairo, Ill.; Secretary, Dr. W. B. La Force, Ottumwa, Iowa; Treasurer, Dr. Emory Lanphear, St. Louis, Mo. Place of meeting, Hannibal, Missouri.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### Throat Affections.

Dr. R. Browning, in *New York Med. Jour.*, recommends the use of iodine in all forms of angina from whatever origin. He, however, does not use it in the form of the pure tincture, in which form it may be applied, but dilutes it with glycerin and water according to the following formula:

|                      |           |    |
|----------------------|-----------|----|
| R. Tinct. iodi ..... | 3ss       | 2  |
| Pot. iodidi .....    | gr. viiss | 5  |
| Acidi carbol. ....   | m. v      | 3  |
| Glycerini .....      | 3ii       | 8  |
| Aquæ q. s. ad. ....  | 3ii       | 60 |

M. Sig.: Apply locally with a swab.

The application of the foregoing should be preceded by an astringent spray of hydrogen dioxid. Care must be observed in applying the iodine solution in the order that none of it drops into the larynx.

### Specific Iritis.

The following combination is recommended by the *Med. Rev. of Reviews*, to be given internally in specific iritis:

|                             |        |    |
|-----------------------------|--------|----|
| R. Hydrarg. biniodidi ..... | gr. vi | 35 |
| Potassii iodidi .....       | 3iss   | 6  |
| Aq. destil. q. s. ad. ....  | 3iii   | 90 |

M. Sig.: One teaspoonful in water after each meal.

### Neurasthenia.

Dr. Wharton Sinkler, of Philadelphia, in *Internat. Med. Mag.*, says: Arsenic, if it does not disturb the digestion, is of value and may be administered in the form of the solution of bromid of gold and arsenic. Phosphorus alone or in combination is indicated in small doses and many patients who suffer from great nervousness, restlessness and irritability are very much helped by the administration of asafetida and the valerianates. He regards the compound sumbul pill of great value. The formula for this pill, as recommended by Dr. William Goodell, is as follows:

|                             |          |      |
|-----------------------------|----------|------|
| R. Extracti sumbul .....    | gr. i    | 06   |
| Ferri sulph. (exsic.) ..... | gr. i    | 06   |
| Asafetidae .....            | gr. ii   | 12   |
| Acidi arsenosi .....        | gr. 1/40 | 0015 |

M. Ft. pillula No. i. Sig.: One such pill three times a day, increasing to five or six a day.

He advises the use of sodium bromid in the depressed, restless and physically nervous cases. This may be given in liquid form, combined as follows:

|                                |       |    |
|--------------------------------|-------|----|
| R. Sodii bromidi .....         | 3iiss | 10 |
| Tinct. nucis vom. ....         | 3iiss | 6  |
| Infusi gentianæ q. s. ad. .... | 3ii   | 60 |

M. Sig.: One teaspoonful three times a day. He emphasizes the danger from keeping up the bromid for any length of time in these cases. Nevertheless, if given at intervals, great good may be accomplished by its use.

### Vaginismus.

The general treatment of vaginismus, according to the *Med. News*, consists of avoidance of intercourse and in taking exercise and warm alkaline baths of soda and starch, using a bath speculum in the vagina. A stimulating diet should be avoided and bromids with valerian or valerianates administered. The local treatment may consist, first, of warm vaginal washes of mercuric bichlorid (1-5000), liquor plumbi subacetatis (1-240), or tincture of calendula (1-20); second, of suppositories containing one of the following ingredients: cocain gr. ii (.12), extract of belladonna gr. ii (.12), extract of hyoscyamus gr. v (.30); third, local applications of iodoform disguised with iodine or ichthyol. Medicated glycerin tampons or a vaginal dilator may be worn at night. Direct applications to the parts of solutions of carbolic acid may be made. If these means fail operative dilatation must be resorted to.

### Inhalations in Tuberculosis.

Dr. J. E. Stubbett, in the *Post-Grad.*, recommends the following combinations for inhalation in addition to the general and systemic treatment:

|                        |       |    |
|------------------------|-------|----|
| R. Olei camphoræ ..... | 3iiss | 10 |
| Terebene .....         |       |    |
| Eucalyptol, aa. ....   | 3i    | 30 |

Sig.: To ten drops to be placed in an inhaler and used once or twice daily; or:

|                              |        |    |
|------------------------------|--------|----|
| R. Menthol .....             |        |    |
| Camphoræ, aa. ....           | gr. xv | 1  |
| Liq. alboleni q. s. ad. .... | 3i     | 30 |

M. Sig.: To be used in the nebulizer once or twice daily; or:

|                              |    |    |
|------------------------------|----|----|
| R. Creosoti .....            | 3i | 4  |
| Liq. alboleni q. s. ad. .... | 3i | 30 |

M. Sig.: In the form of an inhalation. He states that for two or three hours after the use of either of these inhalations the breath gives the odor of the drug used, showing that the bronchial mucous membrane must have been tolerably well saturated.

### Prostatic Congestion.

Stordeur, in *Progrès Méd.*, recommends the following suppository in relieving prostatic congestion from any cause:

|                           |         |    |
|---------------------------|---------|----|
| R. Pot. iodidi .....      | gr. v   | 30 |
| Ichthyol .....            | gr. iii | 20 |
| Morphinæ hydrochlor. .... | gr. 1/6 | 01 |
| Ext. daturæ .....         | gr. 1/6 | 01 |
| Ol. theobromæ, q. s. .... |         |    |

M. Ft. suppository No. i. Sig.: One or two daily.

### Disinfection of a Room.

The following method of disinfection of a room and its contents after scarlet fever or other of the infectious diseases is recommended by the *Cleveland Med. Gaz.*: 1. All cracks or openings in plaster or floor and about the door and windows should be closed by cotton or strips of cloth. 2. The linen, quilts, blankets, carpets, etc., should be stretched out upon a line in order to expose as much surface as possible to the action of the disinfectant. They should not be thrown into a heap. 3. The walls and floor of the room and the articles in it should be thoroughly sprayed with water. 4. For each 1000 cubic feet of space, 150 centimeters (five ounces) of formalin should be placed in the distilling apparatus and distilled as rapidly as possible. The keyhole and spaces about the door should then be packed with cotton or cloth. 5. The room should then remain closed for at least ten hours. If there is much leaking of gas into surrounding rooms a second or third injection of formaldehyd at intervals of two or three hours should be made.

### Echymosis.

Periocular echymosis or what is termed "black eye" is best treated, according to Wood in *Med. Standard*, by the application of ice compresses if seen soon after the injury, or with an evaporating lotion composed of the following:

|                              |     |     |
|------------------------------|-----|-----|
| R. Liq. plumbi subacet. .... | 3i  | 4   |
| Alcoholis .....              | 3i  | 4   |
| Aq. destil. q. s. ad. ....   | O i | 480 |

M. Sig.: Apply locally to the affected parts.

Where a definite blood clot has formed within the palpebral tissues, the common practice of incising the skin and allowing the blood to escape or applying two or three leeches to the orbital margin is a good one. An antiseptic dressing should be subsequently applied. Unless treatment is resorted to within two days, no remedy will be of use.

### Chronic Gastric Catarrh.

C. A. Ewald, as noted in *Medicine*, states, in the treatment of gastric catarrh, that two conditions are to be met: 1. A diminution of hydrochloric acid and pepsin; 2, lessened motility of the stomach. As a result of these two factors fermentation occurs, the character of which is determined by the kind of micro-organisms present. The disturbance of the secretory function of the gastric mucous membrane is best met by the administration of as much acid as the patient can tolerate, administering it at intervals of ten minutes after meals. In some cases in which the stomach tube is well borne, a 0.2 per cent. solution of hydrochloric acid may be introduced directly into the stomach;

this amount corresponds with the normal quantity. Bitter tonics directly excite and increase the secretion and activity of the cells. The best tonic to produce such secretory effects is conduranga. And to increase the motility strychnia or nuxvomica is the best. The latter is best given in the form of the tincture; massage and electricity are useful adjuncts. In treating fermentations the stomach should always be washed out. A weak antiseptic solution consisting of boric or salicylic acid in 2 per cent. strength should be employed. Fermentations may be inhibited by the following:

|                                |           |    |
|--------------------------------|-----------|----|
| R. Resorcin (resublimed) ..... | gr. viiss | 15 |
| Bismuthi salicylatis .....     | 3iiss     | 10 |
| Natrii bicarbonatis .....      | 3iv       | 15 |
| Sacchari albi .....            | 3iv       | 15 |

M. Sig.: A small teaspoonful every two hours.

According to his statement no recovery is possible without a proper regulation of the diet. The patient should thoroughly masticate the food. White meats are more digestible than red meats. Fat meats should be entirely avoided. A limited amount of white meat may be taken, such as poultry, which is more digestible than the red meats. Eggs are sometimes agreeable to the patient's stomach. Milk is the best diet when agreeable to the patient. The starches should be converted into dextrin if possible. Vegetables are very well taken and digested, especially if cooked in salted water. However, vegetables such as cabbage, peas and beans are, as a rule, not well borne.

## Medicolegal.

**Neglect of Injured Employee While Being Taken Home.**—The Supreme Court of Rhode Island holds, in the case of *Bresnahan vs. the Lonsdale Company*, that a cause of action was sufficiently stated in the allegation that the company undertook to convey a certain person to his home after his injury, and neglected to take the proper precautions to cover and protect him while so doing, in consequence of which exposure complications ensued, causing his death. If the taking home of the party after his injury was a duty assumed by the company, the fellow-servant doctrine contended for by it, probably to the effect that the negligence being that of fellow servants it would be a risk assumed by the injured employee and not something for which the employer would be responsible, the court holds did not apply.

**Duty of City to Pay County Health Officer.**—The Court of Appeals of Kentucky says that the object of the case of *Blair vs. the City of Middlesboro* was to recover \$600 for services rendered by a physician as member of the County Board of Health, whose services as health officer were rendered in the city in the midst of a smallpox epidemic. The court says that it seems to it that sections 2059 and 2060 of the Kentucky statutes made it the duty of the city to procure and have rendered such services as the party suing rendered for it. It might, doubtless, by proper proceedings, have established a board of health, and placed such board of health or health officer in charge, and caused them to have rendered the service which was rendered in this case. But it appeared that no such steps were taken. On the contrary, the city, through its council, accepted and practically ratified the action and services and accepted the same at the hands of the party suing. Under which circumstances, the court is of the opinion that the city was legally bound therefor.

**Aggravation of Injury by Not Observing Instructions.**—The Supreme Court of Michigan says that there was testimony in the personal injury case of *Zibbell vs. the City of Grand Rapids* that the party suing, after receiving the injury, called a surgeon to treat her limb, and that he advised rest for the knee. There was also testimony that she did use her limb to some extent. The trial judge instructed the jury that the party was not entitled to recover any damages for any disability, suffering, or expense that resulted from her own failure to exercise proper and reasonable care after she received the injury of which she complained, which aggravated

her condition, by failure to observe the instructions of her physician, and that the city was not to be held responsible for damages resulting from such neglect on her part. This instruction, the Supreme Court holds, correctly embodied the law. But it holds that it was error, when counsel attempted to argue this question to the jury, for the judge to stop him with the statement that he would charge that there was no act of the party which aggravated her condition. The testimony, it says, was for the jury, and, while it might not have been very convincing that she had been guilty of any imprudence, it should not have been wholly withdrawn from the consideration of the jury.

**Wisconsin Law in Confusion—Use of Title of Doctor.**—The Supreme Court of Wisconsin says, in the appealed case of *Schaeffer vs. State*, that the statutes in relation to persons practicing medicine and surgery in that state are in considerable confusion. Nor does it attempt to untangle them in this case. This was a prosecution under sections 1436 and 4603a of the Revised Statutes of Wisconsin of 1898. The first section mentioned provides, in substance, that no person practicing physic or surgery shall have the right to collect fees for his services or testify in a professional capacity in any case "unless he, before the 20th day of April, 1897, received a diploma from some incorporated medical society or college, or shall since said date have received a license from the state board of medical examiners." Section 4603a provides that any person prohibited by section 1436 from testifying in his professional capacity as a physician or surgeon, who shall assume the title of doctor under circumstances detailed therein, shall be punished by fine or imprisonment, and the burden of showing his right to use any such title shall be upon the accused. The complaint in this case charged that the party in question unlawfully used the title of doctor without having obtained a license from the state board of examiners. The Supreme Court holds that this did not describe an offense under the statutes. It says that the offense consists in assuming the title by one not having a diploma or license. The offense charged was that of having no license. Certainly this did not describe the offense prescribed in the statute.

**Testimony by Patient—Physician Accompanying Another.**—The Supreme Court of Wisconsin does not uphold the contention in the personal injury case of *Green vs. the Town of Nebagamain* that, because the party suing testified in her own behalf as to her condition while she was attended by a certain physician after her injury, she had thereby waived her right to exclude him from testifying on the same subject. It says that if such a rule were to prevail, it would destroy the privilege secured by the statute, or preclude the patient from testifying in her own behalf. There may be adjudications in other jurisdictions, under different or even similar statutes, holding otherwise, but, if so, this court declines to follow them. Then, too, there was in this instance a physician called from another place to treat this party for her injuries. On reaching the town where she was, he requested a physician there, who had been her physician but who had sold out his business with the view of moving away, to accompany him upon his proposed examination. This the latter did, and in his presence, that is, as the court says, in the presence of one who was thus called in as another physician, the physician who was summoned to treat the case made an examination, and prescribed for the party as her physician. The accompanying physician made no examination, and did not remain at the house after the other left. Now, it is very obvious, says the court, that had the physician called to treat the case been offered as a witness on the other side, his testimony as to what he learned upon the examination might have been properly excluded upon the same theory as that of the physician first mentioned in the case. It holds that the same was also true in respect to the proposed testimony of the accompanying physician just mentioned. It says that he had "been called in as another physician" by an attending physician. And it says that it must hold that he was, on account of this, an attending physician, and hence precluded from disclosing any information thus acquired, against the object of the patient.

1. **Cholelithiasis, Cholecystitis and Cholangitis.**—Thomson remarks that scarcely one out of twenty, or in his experience one out of thirty, of those who suffer from gallstones will ever need to undergo operation. The difference between renal calculus and gallstone is that the former is a stone and the latter is a soluble material which in many cases is disintegrated and carried away. Oils readily dissolve biliary calculi outside the body, and it is possible to believe that something analogous takes place within the body. There are only three ways in which the offending gallstone can be disposed of. The least common one is for the calculus to be discharged into the intestine. The second one is for it to float back into the gall-bladder and remain there, as 95 per cent. of the gallstones do. The third is that the bile itself in time dissolves the calculus into a detritus, which is finally expelled without notice. The last process he thinks is more common than generally supposed, and if so, one of the chief indications in the treatment is to increase as much as possible the flow of common bile. Gallstones do not come out of the liver, and are not formed of bile. The first indication in the treatment of cholelithiasis is to prevent bacterial invasion from the intestines: the commonest condition which favors this infection is chronic constipation. He thinks this is the reason many saline laxative waters have gained such reputation in the treatment. Weekly or bi-weekly mercurial purgatives taken at night are also of the greatest value for intestinal antiseptics and he never fails to employ them. We may safely rate sodium salicylate and sodium benzoate as true chologogues. He gives these together in doses of 10 gr. each one hour after meals. In old persons with thickened arteries and weak hearts four or five grains of sodium iodid is a good addition to the sodium salicylate. Olive oil properly administered is the most efficient agent against gallstones, but the old idea of its action is wrong. The way it acts is to cause a watery flow from mucous membranes. Its action in cholelithiasis he conceives to be this: in the first place it is a food oil, and if taken in a small quantity, not over one or two ounces at a single dose, it excites an increased flow of normal secretions, viz., the biliary, the pancreatic and the secretions of Brunner's glands. Not more than an ounce or two is needed or required. In patients with cholelithiasis the dose is taken for ten consecutive nights, then intermitted for about a week to avoid gastric disturbance, and then resumed again for ten more nights. The result is not immediate relief, but a progressive amelioration of symptoms with the paroxysmal attacks becoming lighter and fewer until they cease permanently. The gastric conditions accompanying cholelithiasis require careful treatment. On general principles the patient should avoid

what he finds difficult to digest. If the gastric digestion is in a fair condition rigid dieting is unequalled for. For subacute gastritis he has found 1/20 of a grain of bichromate of potassium and three grains of bismuth half an hour before meals, with five grains of resorcin in solution half an hour after meals, very serviceable. The chief dangers of cholelithiasis are a violent sepsis causing suppuration and ulceration. Some of these call for surgical interference. Among the danger signals he would put continued fever first; the marked irregularity of sepsis being conjoined with the continuousness of true sepsis. It is mainly from infective processes and not from gallstones *per se* that these perils supervene, hence the diagnostic value of fever. Febrile states, cholelithiasis accompanying, are of serious importance. In impacted gallstones the symptoms are usually definite enough. Cholecystitis is next mentioned; whatever its form, it is usually due to infection and in the chronic form the local tenderness is more persistent and not in such definite points as in cases of cholelithiasis. Acute cholecystitis may come on as suddenly as gallstone colic, with severe paroxysms, pain, vomiting, chills and high fever. The tenderness, however, is more diffused than in gallstones and commonly involves the epigastrium, which often projects like a tumor. The liver also becomes large and tender. Jaundice may be absent or insignificant. In mild cases the fever subsides early. Contrasting with these are the forms called fulminating cholecystitis. The patient rapidly shows signs of general poisoning and may become moribund within thirty or forty hours. Suppurative cholangitis is almost always an accident supervening on chronic cholangitis caused by retained gallstones. It is fortunately not a very common affection and not absolutely fatal, though such has been to some extent its reputation. Rare cases may recover.

3. **Notification of Phthisis.**—Shurly thinks that tuberculosis is not specially contagious or is only made communicable through neglect. He does not have much faith in house infection. He points out a number of objections to notification. In the first place, it can not be kept secret and would create embarrassment and often serious hardship to patients. If an erroneous diagnosis had been made, which is quite possible, great injustice would be done and it would cost the state an immense sum of money to support and pay damages to the sequestered people. Our statistics are far from being accurate, but ordinarily phthisis pulmonalis is not as fatal as cancer, pneumonia or infantile diarrhea; not so prevalent as influenza or typhoid fever and not so dangerous to the public health as smallpox, scarlet fever, diphtheria and syphilis.

4. **Osteitis of the Knee.**—From the results of his studies Taylor concludes: 1. Gonitis in childhood usually causes lengthening of the affected limb when approximately straight; this may persist for eight years or more. 2. This lengthening is mainly due to overgrowth of the femur, and may often be detected within six months of the onset. In adolescents and adults, after cessation of active disease begun in childhood, the femur and limb may be considerably shortened. 3. The tibiae are usually equal in length in the early stages; afterward the affected tibia may be slightly longer for a time, but is more often shorter, even in the first two years; this shortening increases in the older cases, and after subsidence of inflammation. 4. With limbs of equal length and duration of disease of several years, the femur of the affected side will be found longer, the tibia shorter than its mate. 5. The feet and patellae show a difference in favor of the sound side after a year's duration and often before. 6. Stimulation of growth at the lower end of the affected femur and, more rarely and in less degree, at the upper end of the tibia is usually accompanied by retarded growth in other parts of the limb; growth in the femur itself is finally retarded, and the final result, after many years, may be considerable shortening of the femur, tibia and limb.

6. **Dry Points vs. Glycerinated Virus.**—Rosenau has investigated the bacteriology of dry points vs. glycerinated virus from various manufacturers to determine which is freest from impurities. He describes his methods of examination; the summary of his results is as follows: "Of 41 dry points examined

we found an average of 4807 bacteria per point. Of 51 glycerinated tubes and capsules we found an average of 2865 bacteria each. This is in excess of what a good glycerinated virus should contain. This difference in numbers does not justify the confidence placed in the glycerinated virus over the dry points as found upon the market, judging from the limited number of counts made. So far as the kinds of organisms are concerned, we found pus cocci in both the dry points and the glycerinated virus. We think we have demonstrated that some of the glycerinated virus on the market is "green"—that is, not kept a sufficient length of time before it is sold. From our studies we have concluded that we ought not to discredit glycerinated virus, for we consider the superiority of the virus amply demonstrated, but to condemn the practice of manufacturers who place an unripe product on the market. Much of the vaccine sold must have a high initial contamination to contain an average of 2865 bacteria per tube, and it is evident too great a reliance is placed upon the glycerin."

**7. Ocular Affections of Diabetes.**—The findings of Pyle's article are summed up by him as follows: 1. Diabetes mellitus or any other disturbance of carbohydrate metabolism may affect any portion of the visual apparatus. 2. The ocular changes may be produced by chemie or physical means, or indirectly through the associated general debility. 3. They may vary in intensity from slight failure of accommodation to a formidable hemorrhagic retinitis and total optic nerve atrophy. Minor visual disturbances are often aggravated by fatigue or increased cardiac action and may improve after rest or decrease of the vascular tension. 4. The intra-ocular disturbances may be exclusively unilateral and there is never seen ophthalmoscopically inflammation of the optic nerve—important differences from the changes in albuminuria, syphilis and other blood-dyscrasias. 5. Albuminuria does not infrequently co-exist with glycosuria and the retinal changes may present a mixed picture or a typical albuminuric retinitis may occur in diabetes. 6. Central amblyopia may exist in glycosuria entirely independent of the toxic influence of alcohol and tobacco, or in habitual users these may become a prominent factor in the causation. In these cases the initial lesion may be in the retinal ganglion cells; the inflammation of the "papillomacular fibers" of the temporal half of the optic nerve being secondary. 7. In chronic glycosuria, with the exception of cataract, ocular symptoms are often present when the constitutional and urinary symptoms are not marked. 8. The ocular symptoms may be the first to lead the patient to seek medical advice, therefore glycosuria should be suspected in the following conditions: (a) Premature presbyopia. (b) Unexplained mydriasis or cycloplegia. (c) Sudden change in the refraction; particularly, marked development or increase of myopia past middle age, without cataractous changes. (d) Intractable iritis. (e) Cataract in young or middle-aged persons. An examination of the urine is advisable even in cases of senile cataract, as the etiology has a bearing on the prognosis of operation. (f) Retinitis, particularly of the hemorrhagic variety. (g) Unexplained optic nerve atrophy. (h) Sudden and marked amblyopia, particularly central, without visible fundus changes. 9. The prognostic significance of ocular disturbance is not definitely established on account of the great difficulty in pathogenesis, severity and ultimate issue of the various forms of glycosuria. In well-marked cases many forms of eye lesions may improve and the patient's general health may be restored. The ocular symptoms do not progress according to any rules. Hemorrhagic retinitis and amaurosis preliminary to coma are the most serious symptoms. The ophthalmoscopic observation of greatest value in the prognosis is the state of the retinal vessels, as this may be taken as an index to the patient's general vascular condition.

**9. Suppurative Tonsillitis.**—After discussing the subject and describing the parts and condition, Hartz summarizes as follows: The obstruction of the orifice of the supratonsillar fossa and the orifices of the crypts of the tonsils predisposes to circumtonsillar suppuration directly, and any vulnerable part of the organism remotely. Early incision should be done at the point of origin, which is usually within the supratonsillar

fossæ or within the crypts of the tonsils. Chronic latent tonsillar abscesses may initiate an infection developing pneumonia, pleurisy, pyemia or septicemia. The cocci variety of germs may be temporarily encapsulated within a wall of connective tissue. Articular rheumatism, consecutive to tonsillitis, is a suppurative process produced by invasion of cocci through lymph or blood channels. Uricacidemia does not cause suppuration, but may predispose to it.

**11. Hemostasis of the Hip-Joint Disarticulation.**—The method described by Sheldon is offered by him as a modification of Senn's, consisting in a primary disarticulation of the head of the femur, followed by the introduction of an artery forceps into the wound behind the femur and cramping the femoral vessels. The several steps are given as: 1. disarticulation of the femur; 2. freeing the upper part of the femur from its muscular and ligamentous attachments; 3. clamping the femoral vessels; 4. formation of the flaps and removal of the limb; 5, ligation of vessels and closing of the wound. The operation is described in detail. The advantages he claims for it are that it is more rapid than any other method, any size or shaped flaps desired can be cut, no constrictor is present to obstruct the field of operation and only the simplest instruments are required.

**13. Vaccination in Porto Rico.**—Ames describes the methods in Porto Rico and the practicability and advisability of compulsory vaccination. In October, 1898, smallpox was endemic, in December it was epidemic, in January, 1899, it had honeycombed the island; in February there were 3000 cases and the disease was spreading. Systematic compulsory vaccination was begun in February and carried on for four months until July 1, when 860,000 vaccinations had been made in a population of 960,000, with 87.5 per cent. of successes. The disease then had practically disappeared. In the two and a half years that have since passed the former average death rate of 621 per annum has been reduced to 2 in a population of over 1,000,000.

**14. Myocarditis.**—Musser relates the symptoms of chronic myocarditis, narrates cases and says that there may be no symptoms in the advanced stage of the disease. It may make its appearance during the course of an infection. The clinical expression also may be effaced or obscured by the phenomena of primary valvulitis, nephritis, an emphysema, or an arteriosclerosis. The clinical expression may also be a symptom of senility. The cardiac symptoms he discusses are heart tire, by local anemia, digestive disturbances, renal insufficiency, breathlessness, edema of the feet, syncopal attacks or angular weakness, tachycardia, small and feeble pulse, etc. The symptoms of cardiac dilatation also soon appear as well as angina pectoris, which may occur only once with fatal results. The patient who has had one attack of angina pectoris is almost invariably doomed. He would say that eight to twelve months was the average duration of life after the first attack.

**15. The Sanitary Condition of Street Cars in New York.**—Soper notes the dangers of street cars, their overcrowded condition, proof of inefficiency of ventilation, the bacterial condition of the air of the cars, the condition in tunnels and subways, in which not only tuberculosis, but other infections, such as measles, scarlet fever and diphtheria, are liable to be conveyed. The principal objects, toward which efforts to improve the sanitary condition of street cars should be directed, are the reduction of overcrowding, prevention of spitting and the proper ventilation of cars.

**16. Anesthesia in the Plethoric.**—Maduro states that the object of his paper is to prove that there are dangers connected with the administration of anesthetics in the plethoric which can usually be overcome by care. The combination of anesthetics, nitrous oxid first and ether following, or chloroform finally if necessary, is suggested. Pharyngeal stertor is sometimes observed and while alarming is usually overcome by pulling the jaw forward and should give no concern. Where the heart's action becomes enfeebled from hemorrhage or vomiting we should look for proper drainage of the mouth and be sure

of deep narcosis before the beginning of the operation. Fear on the part of the patient is usually an element to be considered, and many plethoric individuals think they will not be able to stand the anesthetic on account of difficulty in breathing; thus the natural difficulty is exaggerated by fear. The patient should be assured that deep and regular breathing ensures good results. The narcotic to be used should abolish consciousness quickly and should be followed up by one that is the best cardiac stimulant, like ether.

**17. Counting Blood Corpuscles.**—The various difficulties in counting the blood corpuscles and estimating their number from stained specimens are noticed by Einhorn and Laporte, who give their own methods. In obtaining the blood it should flow out naturally, should not be pressed out and should be evenly stained. Preparations made by spreading the blood on a slide by means of a spreader or by allowing the blood to spread out by force of capillarity between two cover-glasses are not suited to the purpose on account of the uneven distribution of the corpuscles. All their specimens were stained for two minutes by means of the Jenner stain, which is a universal one, bringing out all the various forms. They have found the medium dry objective (DD or E of Zeiss or 5, 6, or 7 of Leitz) with a weaker and stronger eyepiece most practicable. The method of giving the count is as follows: "After preparing the cover-glass specimen and selecting a suitable area, as described above, we count with objective DD and eyepiece 2 all leucocytes visible in the field. After changing eyepiece 2 for eyepiece 4, into which we have placed our blood-counting diaphragm, all the erythrocytes visible in the entire square aperture or some part of it are counted, without having moved the specimen. Now we reinsert eyepiece 2 and move the slide for the width of one field. This procedure is repeated until about six square millimeters (25 fields) have been counted. From these figures the number of leucocytes and erythrocytes in one square millimeter of the cover-glass specimen is calculated. The number of leucocytes in one square millimeter is found by simply dividing their total number counted by the number of square millimeters counted. With the red we proceed in the same manner except that we have to multiply the resulting quotient by the number which indicates how many times the field of eyepiece 2 is larger than that of the field embraced by the square aperture of the blood-counting diaphragm in eyepiece 4. In our case this number was 20.3. All we have to do now in order to obtain the number of corpuscles in a cubic millimeter is to multiply the numbers counted in one square millimeter by the average factors (500 for the red and 400 for the white cells). Lately we have modified the blood-counting diaphragm by substituting a glass disk for the metal part, leaving the arrangement for the square (3 mm.) as before described, the square being formed by lines cut in the glass disk. In this way the blood-counting diaphragm enables us to count the white and the red cells without change of eyepiece."

**18. Medicolegal Relations of Arsenic.**—This special article by Leffmann discusses a recent murder case in New Jersey in which, according to reports, the first trial ended in the conviction of the prisoner and in the second acquittal was obtained on the basis of the possibility of the introduction into the body after death of arsenic, zinc, etc. He thinks we should take more notice of the modern custom of undertakers and regulate the use of arsenical fluids—at least enough to prevent embarrassing medicolegal inquiry. He says that to prove death by arsenic some pathologic condition characteristic of its action must be shown. It can not be now assumed that 2 gr. of arsenous oxid will cause death in an adult, nor that the mere finding of arsenic in the abdominal viscera proves that the poison was introduced before death.

**19. Perineal Prostatectomy.**—After an elaborate description of the anatomy of the prostate and its relation to the genito-urinary organs, Deaver reviews the methods for the relief of its hypertrophy, first comparing methods of castration. Vasectomy and castration are practically becoming obsolete, though they are still worth trying in cases seen too late and where a more radical procedure would be unjustifiable. Suprapubic prostatectomy has its disadvantages in requiring work

to be done through the bladder wall, in many cases blindly, where thick abdominal walls and contracted bladder exist. In certain cases, however, it may be indicated. Bottini's operation is also conducted in the dark and its statistics do not show it to be an unusually valuable one. He declares perineal prostatectomy to be based on sound principles, sound anatomically because the posterior portion of the prostatic urethra is removed, thus allowing easy access to the new growths. The base of the bladder and the internal sphincter are not damaged, and free drainage is secured; the capsule of the gland, to which the supports of the bladder are in a great measure attached, is left, and, what is most important, the entire seat of the trouble and all new growths are certainly and radically removed. Septic cystitis, unless pre-existing, is not likely to follow because the bladder is not injured. Even the danger of the sudden relief of a distended bladder may be obviated if we are careful not to encroach upon the internal sphincter. The operation is an extensive surgical procedure, and is described in detail. It necessarily destroys the procreative powers of the individual—a fact which must be considered before operation is attempted—but on the whole he thinks the method more suitable to earlier cases than those in which periprostatitis has made operation difficult and prolonged sepsis from cystitis and pyelitis has rendered the patient unfit for any major surgical procedure.

**20. Post-Operative Neurasthenia.**—The subject is thought by Burr to be of sufficient importance to be considered by surgeons, and he calls attention to some special points. He thinks that shock and disease are both responsible for it, but the really important question is the propriety or necessity of preliminary treatment of a woman suffering from chronic, especially pelvic disease, more or less serious, but not immediately disastrous to life, in order to shorten the convalescence and hasten recovery. Many of these cases produce neurasthenic symptoms which are increased by hasty operations without preparation of the patient. The removal of the organic disease does not immediately make the patient well. It is often better to put the patient through a course of general treatment and operate later. He therefore advises the use of the rest cure, with close medical supervision for every indication that may appear, for some weeks before operation, regulation of the nature and amount of the diet, exercise by proper massage and Faradism. In this way the shock of the operation will be lost and recovery secured. Sometimes operation may be avoided entirely.

**22. The Bacteriology of Erysipelas.**—Pfahler describes the diplococcus on which he published an article in the *Philadelphia Medical Journal* of Jan. 13, 1900, and which he has since further investigated, making a series of 98 cases altogether. In a number of these, aseptic applications had been previously made which had probably affected a number of foreign organisms on the surface of the skin, but the diplococci were found in 86 of the 98 and in pure culture in 66. The cocci were spherical, usually occurring in pairs, often singly, rarely in fours. They stained readily by anilin, gentian-violet, carbol-fuchsin and by Gram's method, but did not stain well with Loeffler's alkaline solution of methylene blue and still less with a saturated aqueous solution or with Gabbett's solution. The microbe grows in the presence of oxygen and at room temperature, but better at 31 C. It is non-motile. Cultures in bouillon show a cloudiness at the end of twelve hours, which increases from day to day, but which tends to clear after several weeks, leaving a sediment. It also forms minute opaque colonies in glycerin-agar at the end of twenty-four hours and a more luxuriant growth on blood serum. Gelatin is not liquefied and there is no evidence of gas production. The inoculation experiments produced, as a rule, a perfect area of erysipelatos inflammation. In only one case did inoculation fail in rabbits. In guinea-pigs and white rats it seems ineffective. He claims that Koch's postulates have been demonstrated with reference to this organism as follows: 1. It was found in the diseased tissues of 86 different cases of erysipelas. 2. It was grown upon artificial media in each case. 3. The disease was produced in 24 rabbits by subcutaneous inoculations. 4. The

same organism was obtained from the diseased tissues of the inoculated animals.

**26. Leprosy.**—Montgomery reports an interesting history through three generations. The parents were missionaries in the Sandwich Islands. The father's death was possibly from blood poisoning and his family was markedly neurotic, one sister, it is said, having become permanently insane. There was no history of disease in the missionary's wife or in her family. Of eight children five were females, four of them healthy; one a maculo-anesthetic leper who recovered. Of the three males, one died in youth, another died at six months from perforating ulcer of the wrist, the third had maculo-anesthetic and possibly tuberculous leprosy with recovery. The one female leper bore five healthy children. Three of these were lepers and recovered. Another healthy member of the family had five children, one of them a leper. The one male leper had two sickly children that died in infancy, two healthy children and one healthy grandchild. The cases are given in detail. The recovery seemed to have been sufficiently marked to warrant the designation. The author does not believe in the heredity of the disease in these cases; there were evidences enough of possible contagion.

**27. Peritonsillar Abscess.**—Barstow wishes to draw attention to the treatment used by him in 10 of his cases during the past two years which has thus far given good results. Two of the patients have had complete immunity from the attacks for two years, one for one year, two for six months and one case failed. Five have been lost sight of. The object of the treatment is, briefly, to open up the supratonsillar recess so widely that it will drain itself freely, repair its diseased mucous membrane and cease to be a catch-all for germs and debris. This result is accomplished as follows: A 4 per cent. solution of cocaine is injected from a hypodermic syringe into the body of the tonsil and into the peritonsillar region, through several points in the anterior pillar. This gives a degree of anesthesia quite sufficient for the operation. Then, with a bistoury, a curved incision is made from above downward, dividing the plica triangularis at its base from the anterior pillar. Next, with a Myles tonsil punch, the entire upper part of the tonsil is removed piecemeal, together with a part or the whole of the plica triangularis. If the instrument be sharp and in good order, the operation is entirely painless. A dull instrument, however, pulls like a dull pair of barber's scissors and this is exquisitely painful. The earlier part of the operation is quite easy. Toward the end, however, it becomes necessary to burrow quite deeply between the pillars, and there is danger, on the one hand, of failure to accomplish the desired end; on the other hand, of wounding one of the pillars and causing hemorrhage. If, however, the tongue be smartly depressed, the patient, in gagging, turns the stump of the tonsil forward toward the operator, and the operation can be finished, step by step, under his eye. When neatly and carefully done, the operation is quite painless and the resulting sore throat very trifling. It is not always possible to avoid wounding the pillars of the fauces, and when this happens there is always soreness and there may be hemorrhage. Dr. R. C. Myles has shown that hemorrhage after tonsillotomy is very rare, except when the pillars are wounded, for the tonsillar arteries are small terminal twigs and there is no vessel which passes through the tonsil to supply other structures. Only very rarely, and with an unusually restless patient, it is necessary to divide the operation into two sittings. The usual time consumed is less than fifteen minutes, and most patients bear the strain without much trouble. Should it, however, be necessary to remove both tonsils, it is better not to attempt both on the same day.

**29. Penetration of the Body by Actinic Light.**—Gottheil and Franklin have experimented with the effects of ordinary actinic light by the violet end of the spectrum and offer the following conclusions: 1. Light, in proper concentration from a source of sufficient actinic power, can be made to penetrate the entire thickness of the human body, including both surfaces of the skin; hence all the internal organs are accessible to its influence. 2. Since no portion of the interior of the body, how-

ever, can be more than half the thickness of the frame from a cutaneous surface, and much of it is much closer, the time required for efficient actinic penetration to any depth is only a fraction of that employed in the experiments; conversely, if the time employed is equal, the chemotaxic effect will be far greater. 3. The proof of the penetration of actinic light to and through the internal organs apparently opens a field for its successful employment as a therapeutic agent in internal maladies, in view of its admitted efficacy in a number of external affections.

**31. Asepsis in Dentistry.**—Incited by the remark of a New York surgeon that no New York dentists paid any attention to asepsis, Lederer gives his methods in dental practice and thinks the speaker will not feel justified in repeating his remark. The hands, he says, are cleansed with hot water and green soap. If a patient turns up who is suspected of specific infection, he makes it a practice to use finger cots, sterilized before and after using. Forceps and all larger instruments are sterilized by boiling in formaldehyd solution before and after use. Hypodermic needle, nerve broaches and engine drills are passed through alcohol and burned off, then, before being introduced, are dipped in carbolic acid, full strength. For syphilitics, a separate set of instruments is employed. He describes the details, to illustrate his method of aseptic dentistry, in four cases, one of extraction, one of caries, one of pyorrhea alveolaris and a case of alveolar abscess.

**36. Appendicitis.**—Richardson's article is devoted to the diagnosis between appendicitis and thoracic conditions, and says that it is possible to make glaring errors. In all right-sided conditions of the thorax the symptoms may be so atypical that unless the surgeon makes thoracic examinations an invariable rule, he may be liable to explore the appendix in cases of pleurisy or pneumonia. He illustrates this by cases. The possible quick infection of the pleura from an appendicular lesion must also always be considered. The real cases of appendicitis or general peritonitis as compared with those of atypical typhoid or pneumonia or some other simulating condition are about 100 to 1. If, in cases of doubt, the rule is to operate, more lives will be saved than if the rule is not to operate. The diagnosis between acute thoracic and acute abdominal disease is always easy when the characteristic signs of either are apparent. The chief difficulty in making a decision is to recognize that the necessity for that distinction exists, as the thoracic symptoms are always masked by the more conspicuous and distressing abdominal ones. When once the attention is drawn to the possibility of a thoracic cause the diagnosis is easy.

**37. Carcinoma of the Uterus.**—Pryor notes the essentials of the operation for uterine carcinoma, first, parametrium and upper third of the vagina being removed in all cases of cancer of the cervix and in case of cancer of the body the parametrium only. There are two great dangers facing the surgeon, he either keeps too close to the cancer in avoiding a wound of the ureter, and is therefore not thorough, or in trying to be thorough he risks wounding the ureter in his attempts to keep away from the cancer. He believes in the majority of cases of young women or those under 50 years of age the abdominal operation is greatly to be preferred. He has lost but one woman under that age from preventive ligation and abdominal ablation. In no case has there been recurrence in one year. In the aged, with degenerate vessels and a tendency to less active progress of the disease, operation can be made through the vagina. In case of cancer of the body of the uterus the statistics from vaginal hysterectomy are sufficiently good, but he thinks it is a question whether it is not advisable in younger women to approach cancer of the corpus through the abdomen as in these recurrence is apt to be most rapid. The second requisite in operation—met equally well by both operations—is that no injury should be inflicted on the involved field during its removal; in abdominal operations the adjacent absorbents are cut off before any force is applied to the organs to be removed, hence there is less danger of pressure of the cancer elements into them. Extraneous circumstances having been considered, he describes the technic of the vaginal operation for

cancer of the corpus and find there is a distinct indication for vaginal hysterectomy in cancer of the cervix, but in a limited percentage of cases. It is, however, the operation of choice in cancer of the body of the uterus in nearly all cases, excepting young women with pus foci and those with cancer associated with fibroids.

**39. Abdominal Hysterectomy for Uterine Cancer.**—Irish believes that vaginal hysterectomy should be discarded in cancer of the cervix and that abdominal hysterectomy is the only resource left, that abdominal hysterectomy fulfills all operative requirements and whatever advance is made in treatment must be outside of the matter of operation. The only improvement we can hope for in the operative way is in wider dissection of pelvic lymphatics and glands than many surgeons now make.

**40. Carcinoma Uteri Complicating Pregnancy and the Puerperium.**—Cumston sums up as follows: If the carcinoma can be radically removed, the life of the mother alone is to be considered. Up to the beginning of the sixth month of pregnancy vaginal hysterectomy is the operation of choice, but after this period is passed, abdominal hysterectomy or Dührssen's vaginal Cesarean section, followed by hysterectomy, are indicated. When the neoplasm is inoperable, the life of the child must be considered, but if the progress of the growth is such that the mother rapidly becomes cachectic, thus compromising the fetal vitality, pregnancy should be interrupted. Palliative treatment only should be instituted, because partial operations on the neoplasm usually produce miscarriage and the mother is not materially benefited by them. Cesarean section at term may be done, but when the uterus is left there is danger of septicemia, consequently Porro's operation is the one of choice if the peri-uterine tissues are not infiltrated to such an extent as to render this procedure dangerous.

**41. Treatment of Unremovable Carcinoma Uteri.**—All we can hope for in cases of unremovable uterine cancer is to keep down cauliflower growths and painful granulations by surgical and local treatment, purify the secretions, prevent auto-infection, allay irritation and as far as possible keep a clean granulated condition of the ulcerative surface. Curetting the urethra with sharp instruments is advised if the patient's strength admits. Hemorrhage is an early as well as a late manifestation, and is, as a rule, treated with the curette and cautery. The bladder complications are distressing and treatment is really of little avail. Under the circumstances one can do little more than keep the patient half-way dry, grease the parts and skin exposed to irritation with a soothing ointment and administer opiates. The bowels should be kept open by salines. Stricture of the bowel with complete occlusion, though frequent in cancer originating in the bowel, is very rarely a complication of uterine cancer. For marked infiltration into the vaginal tissues, when they are fissured and extremely sensitive, hot fomentations and mild unguents are suggested.

**42. Progressive Medical Organization.**—Reed's address congratulates the Physicians' Club of Dayton on the overcoming of prejudice and the general union of honorable and desirable physicians.

**43. Ligation of Arteries.**—Ricketts pleads for the value of cocaine anesthesia in the ligation of arteries and in minor operations of this sort, giving special points in detail of the injections into the nerves supplying different parts.

**45. Middle-Ear Disease in Deaf-Mutism.**—King's article is largely a plea for early attention to oral disease in children and to preserving the power of speech in case the hearing is lost.

**46. Tubercular Enlargement of the Breast.**—Bogges calls attention to enlargement of the breasts during tuberculosis. He says it is not uncommon and is possibly more frequent in males than in females. It is correctly stated in the older books that this condition occurs more frequently on the side of the affected lung. The case he reports was in a little girl in whom there was an appearance of inflammation and threatening suppuration, which, however, did not occur.

**49. Trachoma of the Female Genital Tract.**—Hale believes that certain conditions of the female genital tract are entirely analogous to if not identical with trachoma. He says, "with the pathognomonic indications of a thin, watery discharge, no history of specific infection, the peculiar rice-grain surface of the mucosa from enlarged papillae and bleeding fissures, the persistent vaginismus, the increasing constitutional nervousness from peripheral nerve involvement in the new tissue formation of denuded surfaces, and in well-developed cases of cicatricial formation, oftentimes demanding surgical interference, is it not well to suspect that we have the same condition as is frequently met in conjunctival trachoma and to at least so diagnose this condition until the microscopists throw more light on this affection as well as on that of the ocular mucosa." He has found this state of affairs existing at all ages and remarks that the urethral mucous membrane also is frequently involved because of its proximity. The treatment he advises is thorough cleansing with warm water slightly impregnated with hops, wiping dry with a pledget of aseptic cotton, followed by liberal and oft-repeated applications of hydrogen peroxid rubbed well into the tissues and wiped thoroughly dry. Following this he uses protargol which he finds the most efficient remedy in the proportion of protargol 10 parts, glycerin 40 parts and water 50 parts, applied on a pledget of aseptic cotton. Two cases are reported.

**59. Tendon Transplantation.**—After noticing the literature of tendon transplantation, Elting mentions the various methods by which this is performed: 1. The severed tendon of a healthy muscle is attached to a paralyzed muscle. This has the objection that it sacrifices the normal function of the transplanted tendon. 2. The tendon of the paralyzed muscle is divided and its peripheral portion is attached to the tendon of a healthy muscle. 3. The tendon of a healthy muscle is split and a part is transplanted upon that of the paralyzed muscle. This is the most logical, and when possible, the most satisfactory method. 4. This method consists in attaching the transplanted tendon directly into the periosteum. The advantages claimed are: 1, a more secure attachment of the tendon is obtained where a healthy tendon is sutured to one that is paralyzed and, 2, the greater freedom is allowed in the attachment of the transplanted tendons. The usual method of suturing is that of the Goldthwait, in which the paralyzed tendon is split and the transplanted tendon, having been scored along its edges to promote rapidity of union, is passed through the paralyzed tendon and fastened to it by quilted sutures. Catgut, kangaroo tendon and silk are used as suture material, but silk seems to be the most satisfactory. The lengthening of the tendons is a more desirable procedure than tenotomy, because the continuity of the tendon is not destroyed. In most cases the results are gratifying. A weak muscle can not be made to do normal work, but when it works advantageously it tends to grow stronger and more efficient. In the great majority of cases voluntary control of the new function of the transplanted muscles develops. The cortical cells connected with the muscle divide their activity in such a way as to produce normal control. Where this is lacking, the transplanted tendons tend to hold the foot in a normal position by their mechanical action and the involuntary contractions will furnish the necessary stability. A number of cases are reported.

**62.**—This article has appeared elsewhere. See *THE JOURNAL* for April 26, [13, p. 1108.

**66. Vaccination.**—Fielder, from his studies of the statistics and authorities, concludes that multiple vaccination is a much better protection than that afforded by a single vaccination scar. He holds that after five years or more the protection is lost and that therefore revaccination should be as symmetrically and as conscientiously performed as primary vaccination.

**67. Arteriorenal Disease.**—The principal point of Quimby's article is the effect of toxemia, largely intestinal, on the renal circulation, producing kidney disease; he holds that the persistent disturbance of the normal ratio between solids and fluids in the urine, whether constant or variable, is the earliest symptom of toxemia, and indicates conditions which, if continued,

are certain to develop more or less rapidly cardiorenal disease. The propositions are given as follows: 1. That intestinal toxemia is one of the most common but least appreciated causes of arteriorenal disease. 2. That its more common occurrence in patients of abstemious habits and correct lives, together with the established custom of attributing all chronic renal disease to gout or alcohol, and all arterial fibrosis to high tension or syphilis, have caused us to overlook the symptoms of primary toxemia and to regard the renal and arterial degeneration as primary processes instead of the final stage in a general disease.

**68. Alcohol.**—Dennis' article is a strong exposition of the evils of alcohol, of which he has very little good to say in any way.

**69. Obstetric Forceps.**—The summary of Ayers' article is given as follows: "Use the 'classic' blades whenever they will accomplish delivery without fetal injury. Select the time of application nearest the obstetric moment—completion of cervical dilatation and head molding—permissible by the character of the patient's expulsive powers. Apply the blades to compel anterior rotation of the occiput. In tractions make the first aim delivery of the head through the cervix, rather than its descent into the pelvic brim. Remember that tractions are similar to convulsions in their effect on the fetus, which, prolonged, provoke asphyxiation. Keep the shafts off the perineum during the tractions high up. Remove and reapply the blades at studied intervals in prolonged and difficult cases. Extend the limbs when the head reaches the vulva. Remove the blades when the hands control the head. Keep constant watch of the fetal pulse."

**74. Vesico- and Recto-Vaginal Fistulae.**—The method suggested by Kelly consists in putting the patient in a properly-supported knee-chest position, thorough cleansing of the vagina, opening the vault in the line of the transverse scar through and into the peritoneum, by making a small incision in the attenuated septum. As this is done the air rushes in and the viscera drop towards the diaphragm. This little opening is then extended as widely as possible from side to side, destroying the vaginal vault and setting the bladder free. Next a large gauze pad with a stout thread attached is thrust down into the peritoneum and by pulling on this the bladder is crowded toward the vaginal outlet while the peritoneal cavity above is protected. It is important to wipe out the cavity of the bladder from time to time in order to avoid the escape of any of its contents onto the peritoneum. The margins of the fistula are now split, separating the vagina from the bladder, or if preferred, the fistula is denuded on all sides. An ordinary scalpel or a bistoury can not be used for this; a short-bladed thick knife, set at an angle to the handle and sharpened on both edges, which is illustrated in the paper, is used by Kelly. When the edges are split and the bladder wall set free, the bladder is sewed up separately by means of a row of buried sutures of fine silk or of catgut, uniting the muscularis alone, turning the vesical edges into the cavity of the bladder. The vaginal section is then united with a row of fine silkworm-gut sutures which may be continued up into the peritoneal surface of the bladder, easily and securely covering that part of the fistula which under previous methods was less likely to heal. There must be no dead space left between this and the buried row of sutures. The silkworm sutures are cut off at about 4 cm. from the knot. The fistula being now closed the pack is withdrawn. In order to get rid of the air in the peritoneum, the cavity is filled through a tube with normal saline solution, which, as it rises, displaces the air. When the patient is turned in the dorsal position all the water escapes. A little suturing at each angle and a draia of washed-out iodoform gauze in the middle completes the operation and the dressing. It is best to keep a catheter in the urethra from 7 to 9 days following the operation. Kelly says he has closed several fistulae of this group by opening the peritoneum, but has not as yet made the wide lateral dissection proposed here. The same principle can be applied still better to recto-vaginal fistulae situated high up in the vagina. In this case the absence of the uterus is not needed to facilitate the exposure of the fistula, as it is only

necessary to open the peritoneal cul-de-sac behind the cervix widely from side to side and along the side of the rectum to gain the great advantage of increased mobility of the bowel, including an area above the fistula which can also be turned in by sutures so as to cover in the upper angle of the opening. He prefers in these cases to sew up the bowel separately with fine silk sutures in one or two layers and then he does not attempt to close the vaginal wound over the bowel, but puts a little iodoform gauze drain between the edges and allows the wound to close by granulation. An opening should be left in the peritoneum wide enough to admit a small iodoform gauze drain.

**75. Cyclic Albuminuria.**—Huger's conclusions are as follows: "The cyclic albuminuria, like the recognized pathologic albuminuria, is due to one or perhaps all of three causes: 1, inflammatory and degenerative changes in renal structure, as evidenced by the findings of casts (there is every reason to think that, by careful searching, casts will be found far more often than previous reports lead us to believe); 2, alterations in the quality of the blood which render its serum-albumin more diffusible (there is nothing to prove an inferior diffusibility in these cases, but the patients are almost always anemic); 3, alterations in the degree of blood-pressure, here due to a mechanically-increased pressure on the renal veins. Having learned that occasionally these cyclic cases pass into Bright's disease, but that by far the majority have gotten well and that many have been followed for years and then lost sight of still in the same condition, it must be admitted that Moxon and Arnosan were right in dividing them into two groups: 1, those few which develop a continuous albuminuria, and, 2, the vast majority which get well. Continued rest in bed for a prolonged period should always be urged, because at any rate it removes the exciting cause. One of my cases remained free from albumin for three months after being in bed for three weeks. I believe that, by a very careful examination, a large percentage of cases will be found to contain casts, and that the serious prognosis given because of their presence will be modified."

**84. Middle-Ear Inflammation.**—Meierhof remarks in this paper that early operation, that is, incision of the drum before rupture tends to prevent later complications. There are some cases where early opening of the drum is not sufficient, and where early opening of the mastoid will belong to the prophylaxis of destroying ear disease. The indications for such operation will be found in a much larger number of cases than has been believed. In his experience minor treatment has been sufficient in most cases. Very few cases require major operation where the patient has had the benefit of early expert treatment.

**99. American Decadence.**—Kyger's article follows the lead of Engelmann in claiming that there is a marked decrease in fecundity in the native stock, and calls for reform.

**101. Food Preservation.**—Moechel has continued his experiments with formaldehyd and finds that it has little bad effect on human digestion, at least on pancreatic digestion. All the modifications of formaldehyd have active reducing qualities and exhibit tendencies to combine with proteids. The addition of formaldehyd to milk causes a formation of compounds, but these did not cause a perceptible loss of food value, for the pancreatic digestion causes their complete solution. This, of course, is speaking of combinations in the proportion of 1 to 20,000 or 1 to 40,000. Sulphurous acid and its salts are detrimental, and laws to regulate the use of sulphur and sulphites are imperative. They are distinctly toxic and injurious and should be prohibited in beer, cider, and especially in meat, and only used in wines in definite quantities, under the supervision of a responsible person. The use of fluor preparations should be condemned and prohibited. Salicylic acid, if used at all as a food preservative, demands legislative interference. As regards benzoic acid and sodium benzoate, while perhaps not so objectionable as some other agents, their indiscriminate use should be prohibited by law. Beta-naphthol and hydro-naphthol should not be used as food preservatives. The present state of our knowledge of saccharin does not justify recommendation or condemnation. Pyroligneous acid has not yet received study

upon these lines, but meat preserved with it should not be sold as smoked meat.

**Amebic Dysentery.**—McElroy gives the symptoms and history of amebic dysentery and insists on the importance of microscopic examination of stools, especially in cases resistant to treatment.

**110. Malarial Methemoglobinuria.**—This paper of Krauss is intended to cover such points as have appeared since the last joint paper of Dr. Goltman and himself. He has modified some of his views. He finds that the estivo-autumnal parasite is sometimes the cause of fever and, therefore, it can not be excluded. It is not merely a "plus infection." The index to determine the administration or non-administration of quinin, instead of being as stated, is simply this: so long as sporulating parasites are in the peripheral blood there is no hematuria, therefore push quinin to the limit. He reiterates the conclusion, however, that when hematuria is once begun, quinin has no place. This, however, does not apply to the use of it in tonic doses in the post-hematuria period. At present Krauss does not believe that quinin hematuria is different from the malarial form. The effect of quinin on susceptible individuals seems to him to be due entirely to the amount of the hemolytic body stored up. This varies in different individuals. Some set free their storage after a single dose of quinin; subsequent doses can obviously do no further harm. Some, however, seem never to lose it, as in the cases in which all treatment has to be suspended. How much the liver has to do with this perverted metabolism is not clear, but the previously announced pathology, so far as it has reference to the liver, is clearly erroneous. The record he now gives is of 16 cases treated by the eliminative method to prevent inspissation of urine by using salt solution for injections under the skin. The treatment for the symptoms is morphin fortified with atropin for the tranquillizing effect, strychnin in free dosage, keeping the skin active with tentative doses of pilocarpin, woolen covering, together with the avoidance of drafts and stimulating diuretics. These 16 cases with no deaths contrast favorably with the former report of 12 cases with 9 deaths. Any patient whose kidneys become obstructed necessarily dies. Quinin therapy is not always fatal for reasons given. In one case the continued use of quinin for three days merely resulted in a practical exsanguination of the patient. Salt solution, bone marrow and pepto-mangan were the only agents used after suspension of the quinin; no blood could be obtained at the time and no attempt was made to get it.

**111-112. Continued Fevers of the Mississippi Delta.**—The paper by Sutherland points out the general characters and the species of the continued fevers occurring in the Mississippi delta and the difficulties met in their diagnosis. He thinks there is a partial immunity in these regions against not only typhoid but diphtheria and some other diseases, but he believes that typhoid is not uncommon. He has noticed that non-einchonization with enormous doses of quinin is not a reliable test and that it is more difficult to einchonize typhoid cases in the sense of producing deafness than cases of malarial fever. Evans' article discusses the following questions: 1. Is there a continued form of malarial fever? He answers, yes. 2. Is there a continued fever properly designated as typho-malarial. There have been many cases reported of mixed infection, but it is merely a dispute over names as to whether they should be called typho-malarial or not. 3. Are not some of the conditions ordinarily known as continued fever merely mistakes in diagnosis and due to leukemia, pernicious anemia, septic endocarditis with valvular implantations, tuberculosis, secondary syphilis, trichinosis, etc.? He reviews the conditions of bacterial endocarditis and tuberculosis and mentions certain others, such as secondary syphilis, and finds that there is a bacterial blood infection that is fruitful of errors of diagnosis. Many of the difficult cases, in his opinion, also belong to secondary syphilis or septic infection otherwise than in the blood. As regards the question whether typhoid fever has not caused most of these conditions, he says the symptomatic diagnosis of typhoid fever is rather difficult, but the keynote is the Widal reaction. He finds that there is no unknown or unnamed

fever in which neither malarial or typhoid germs take part, and most of the cases of the supposed group are typhoid modified by malaria. He is not prepared to state whether this modification is in the germ or in the human body itself. The post-malarial continued fevers are usually malaria pure and simple, and the continued fevers left after the above have been subtracted are the following: tuberculosis, pulmonary miliary intoxications, anemia, leukemia and diarrheas.

**120. Bicycle Riding.**—Zuntz says that bicycle riding is contra-indicated in persons with heart defects or arteriosclerosis, though it may serve as a remedy in some disease of the heart as shown by Siegfried of Naueim. Increased respiration and increased consumption of oxygen induced by its use make it advantageous for persons with undeveloped thorax, with phthisic habit or with pleuritic adhesion. In incipient phthisis it may be considered dangerous and advanced phthisis contra-indicates it. The effect on bronchitis is dependent on the avoidance of the inhalation of dust; the question whether cycling may not favor the occurrence of emphysema by the constant expansion of the chest should not be lost sight of. In all forms of nephritis it is contra-indicated and the urine should be carefully watched where there is any tendency in this direction. The reports in regard to gynecologic affections are contradictory. It is certainly to be avoided in all acute inflammations on account of the invariable tugging at the affected organs. It is also unwise during the menstrual period and pregnancy. An unfavorable effect upon the external genitalia may be exerted in either sex by an inappropriate form of saddle.

**121. Changes of Substances in the Organism.**—Wainwright's article is a very long one and highly technical, but the general conclusion seems to be that the most significant alteration of the chemicals in the body is in the production of inert and harmless substances. A law of special significance in pharmacy is the effort of the body to transmute an active substance into an acid. The acids which are produced by pairing or oxidization are resistant to change or, in other words, are inert and this acidifying quality of the organism is of fundamental importance in the synthesis of drugs.

1. Internal Derangements of the Knee.—Robson reports a large number of cases and gives his views in regard to the condition. The operation which he advises is one of the simplest. An oblique incision is made from the interior border of the lower end of the patella downward and backward, down to and through the synovial membrane so as to open the joint freely without dividing either the ligamentum patella or the internal ligament. If the external cartilage be displaced, the incision is, of course, on the outer side of the joint. On retracting the edges of the incision and flexing the knee, displacement at once appears. To seize the loose portion of the cartilage and snip it off by means of scissors is the work of a few minutes, after which the synovial membrane, the capsule of the knee and the skin are separately sutured, the strictest asepsis being observed throughout. It is unnecessary and undesirable to insert the finger into the joint or to syringe the articular cavity. Formerly he used to try to fix the cartilage in position by sutures, but has abandoned this and simply cuts it away and has never seen any inconvenience result from the loss. From his experience he would advise in case of recent injury with signs of internal derangement, treatment of the case as if it were a fractured bone; first replacing it by the ordinary method long ago described by Hey and then fixing the knee in a splint until all the effusion has subsided, afterwards applying plaster or starch bandage and allowing the patient to either rest completely for a month or six weeks or to go about on a Thomas knee splint and later, securing a return of function in the knee by massage and gentle movements. If, after this thorough treatment, there should be any tendency to weakness or recurrence of the displacement he would unhesitatingly advise operation. If thorough treatment has not been adopted in the first place and recurring displacements have called the attention of the physician from the first, he advises operation at once.

2. Biltong.—This is the name given by the South Africans to

a dried meat which Halliburton has investigated as to nutritive qualities. He finds it readily digestible in artificial mixture in a flask. As digestion in the body is still more efficient his experiments show that it is a valuable nutritive substance.

**6. Death from Chloroform.**—This installment of Embley's article discusses the relations of the vagus inhibition as the cause of cardiac failure. Experiments, made as in the former article, are described and the tracings given. The summary of conclusions as to the effect of chloroform upon cardiac and inhibitory mechanism is given as follows: "It was soon found that the sensitiveness of the inhibitory mechanism varied greatly with the methods employed for preparing the animals for connection with the manometer, etc., and that if the animal had been anesthetized by chloroform without morphin in order to perform the surgical work, normal vagus control was more or less completely abolished by the time the record was started. On the other hand, when morphin alone was used prior to the establishment of the connection with the manometer, the vagus control was found to be unimpaired. One hundred and twenty experiments were made to ascertain the part played by vagus inhibition in chloroform poisoning. In 54 cases vagus inhibition embarrassed the circulation to a more or less dangerous extent, and in 33 experiments was the immediate cause of death. To sum up: 1. A heart which has been poisoned by inhalations of chloroform of strength of 2 per cent. and upwards can always be permanently inhibited by stimulation of the vagi with the faradic current when the blood pressure has fallen to about 40 to 50 mm. of mercury pressure. 2. Chloroform raises the excitability of the vagus mechanism, particularly in the early part of the administration. 3. The increased excitability of the vagus mechanism is due to the action of chloroform on the vagus centers, and the inhibitory action is more intense from being exercised upon a heart whose spontaneous excitability is diminished by the action of the chloroform upon it. 4. Chloroform administered to morphinized dogs in air containing not more than 1.5 per cent. of the vapor, after a period of mild excitation, slowly depresses vagus excitability. The excitability may again be raised with more or less readiness, according to the duration of the administration and the endurance of the vagi, by increasing the percentage strength of the chloroform, or by asphyxia. 5. Vagus inhibition is, in dogs, the great factor in the causation of sudden death from chloroform. 6. Dangerous inhibition is liable to occur whenever the strength of chloroform in the air inhaled rises above 2 per cent."

**7. Abiotrophy.**—This is the name given by Gowers to the gradual degeneration or failure of vitality as shown in various conditions, such as baldness or falling out of the hair, diseases of the muscles like muscular atrophy and specially the neuronie failure characterized by sclerosis, the interstitial tissue having apparently an inverse vitality. When the nerve elements decay the connective tissue overgrows. The various forms of degenerative nerve derangements, due to a lack of vitality, which he calls abiotic are noticed, such as infantile atrophy, optic atrophy, spastic paraplegia, Friedrich's disease, paralysis agitans, tabes and paresis.

**9. Typhoid Fever.**—This second lecture by Corfield continues the discussion of the causation of typhoid, particularly the infection by water and milk.

**10. Bile-Duct Obstructions.**—Robson finds that out of some hundreds of cases of cholelithiasis, on which he has operated, the common bile duct has been attacked in one out of every five or six cases. In a few cases the concretion can be manipulated backward into the gall-bladder and then extracted, but this can be done only when the cystic ducts are dilated. He has been able thus far to clear the ducts on 10 occasions. Occasionally a small stone may be pressed into the duodenum, but this is unadvisable, as it may be pushed into the diverticulum of Vater and be missed. In patients too old or too ill to bear cholecystotomy, a rapid cholecystotomy may be performed to relieve the jaundice and also permit solvent injections to be employed, but his experience with this has not been very favorable. Crushing concretions by pressure of the finger and

thumb through the duct walls has been used with some success, but it is only available in soft concretion and may leave fragments that will cause further trouble. Cholecystenterostomy, or short-circuiting the obstruction, should never be performed for gallstones as it leaves the cause untouched and the small opening is apt to contract and to lead to speedy recurrence of symptoms. This has actually occurred in his own practice and in that of other surgeons. If the patient is too ill for choledochotomy, the gall-bladder can be very readily united with the colon with very little disturbance of adhesions: this is a means of giving relief quite as efficacious as the more difficult operation of uniting the gall-bladder and duodenum. This, however, is only possible when the gall-bladder is dilated, which is unusual in cholelithiasis. He has twice united the dilated duct to the intestine and once drained the dilated duct onto the surface, with recovery. Reaching the common duct through the duodenum seemed an ideal operation at first, but he thinks there is a great danger of sepsis by this method owing to the necessary enterotomy and, since his modified operation, he has abandoned it. The only method which is, as a rule, worth relying upon is choledochotomy, and he gives his technic. It requires the help of but one assistant, no special apparatus and the time involved is much reduced. He puts a firm sandbag under the back opposite the liver, which presses the spine and common duct forward so that it is several inches nearer the surface and acts as a Trendelenburg position in pelvic surgery by letting the viscera fall away from the field of operation. He says: "I then make a vertical incision over the middle of the right rectus, the fibers of which are separated by the finger, which I find to be the most expeditious and the most effective method of exposing the gall-bladder and bile ducts; but when it is necessary to open either the common duct or the deeper part of the cystic duct, instead of prolonging the incision downward, as was formerly done, I now carry it upward in the interval between the ensiform cartilage and the right costal margin as high as possible, thus exposing the upper surface of the liver very freely. It will now be found that by lifting the lower border of the liver in bulk (if needful, first drawing the organ downward from under cover of the ribs) the whole of the gall-bladder and the cystic and common ducts are brought close to the surface, and as the gall-bladder is usually strong enough to bear traction, the assistant can take hold of it by fingers or forceps and, by gentle traction, keep the parts well exposed, at the same time that, by means of his left hand with a flat sponge under it, he retracts the left side of the wound and viscera, which would otherwise fall over the common duct and impede the view. It will now be observed that, instead of the gall-bladder and cystic duct making a considerable angle with the common duct, an almost straight passage is found from the opening in the gall-bladder to the entrance of the bile duct into the duodenum and, if adhesions have been thoroughly separated, as they should always be, the surgeon has immediately under his eye the whole length of the ducts with the head of the pancreas and duodenum. So complete is the exposure that, if needful, the peritoneum can be incised and the common duct can be separated from the structures in the free border of the lesser omentum, but this is not necessary except where a growth has to be excised. The surgeon, whose hands are both free, can now, with his left finger and thumb, so manipulate the common duct as to render prominent any concretions, which can be cut down on directly, the edges of the opening in the duct being caught by pressure forceps. The assistant can now take hold of the forceps with his left hand, and that instrument with the sponge will form a sufficient retractor—since the duct is so near the surface. When the duct is incised, there is usually a free flow of bile which, it must be remembered, is probably infective, but a sponge in the kidney pouch and the rapid mopping up of the flowing bile by means of sterilized gauze pads will avoid any soiling of the surrounding parts; if necessary, the bulk of the infected bile can be drawn off by the aspirator either from the gall-bladder or from the common duct above the obstruction before the incision into the duct is made. After removing all obvious concretions, the fingers are passed behind the duodenum and along the course of the hepatic

ducts to feel if other gallstones are hidden there, then a gallstone scoop, the only special instrument that I use, is passed up quite into the primary division of the hepatic duct in the liver and quite down to the duodenal orifice of the common bile duct, and, if thought necessary to insure the opening into the duodenum being patent, a long probe is passed into the bowel. The incision into the bile duct is now closed by an ordinary curved round needle held in the fingers without any needle holder, a continuous catgut suture being used for the margins of the duct proper and a continuous fine green catgut or spun celluloid thread being employed to close the peritoneal edges of the gut. In such cases, where the pancreas is indurated and swollen from chronic pancreatitis and is likely to exert pressure on the common duct for a time, I insert a drainage tube directly into the duct and close the opening around it by a purse-string suture, the tube being fixed into the opening by a catgut stitch, which will hold for about a week, but where this is not done I usually fix a drainage tube into the fundus of the gall-bladder in the same way, as this drains away all infected bile and avoids pressure on the newly sutured opening in the duct." After the operation he usually inserts a gauze drain through a slit drainage tube, bringing it out either through a stab wound in the loin or forward by the side of the gall-bladder drain. The wound is closed in the usual way by continuous catgut sutures, first to the peritoneum and deep rectus sheath and lastly to the skin. In these operations hemorrhage either immediate, consecutive or secondary can not be ignored as a danger and shock, apart from hemorrhage, has next to claim our attention. Sepsis is no longer a special bugbear with modern methods. Robson thinks there is no doubt that in all cholemic conditions the blood becomes so altered that coagulability becomes seriously diminished. He has used Professor Wright's researches on the coagulability of the blood, and in the last two years has employed chlorid of calcium in apparently heroic doses to obtain the real value of the drug, using 30 gr. doses by the mouth and afterwards 60 gr. doses by the rectum twice daily for several days. It is important to ligate all the bleeding points and not to trust simply to forcipressure and, while in non-jaundiced patients adhesions may be simply separated, in these cases he prefers to divide adhesions between ligatures where practicable. Where there is much oozing of blood he prefers tampons of sterilized gauze and perhaps a solution of suprarenal extract to the bleeding surfaces. The best treatment of shock is preventive. The patient should be protected as far as possible from loss of blood, the operation performed on a heated table, the patient well protected from chill and large enemata of normal saline solution with or without stimulants given from 15 to 20 minutes before. The administration of strychnia subcutaneously just before anesthesia is useful and rapidity of operation is important. Cholecystotomy should occupy from one-half to one hour and perhaps a little longer if complicated, but two, three or four hours indicate lack of skill or judgment. After operation a pint of saline solution with one ounce of brandy is given by enema. Strychnia subcutaneously every two hours for several hours is called for. The mortality of his whole series of 60 cholecystotomies is 16.6 per cent., while those subsequent to January 1, 32 in number, show 7.1 per cent. of deaths, which were, he believes, from unpreventable causes, in one case heart disease, another pulmonary congestion and shock; ether anesthesia by the old rubber bag apparatus—since discarded, he thinks having much to do with the case.

**17. Bronchiectasis.**—Acland says his "conclusion is inevitable that, in the adult, bronchiectasis, when once fairly established, is, except in very rare instances, incurable by any method of treatment at present available. In some of the more acute cases in young persons, cure may occasionally result. In chronic cases the distress of the condition can often be greatly relieved and, if the exciting cause of the disease is not progressive, life can frequently be greatly prolonged."

**18. Infantile Ophthalmia.**—The measures which at the present time seem best qualified to reduce the amount of blindness are summarized by Collins as follows: "1. Compulsory

notification of cases of ophthalmia neonatorum by all persons attending women in labor other than medical men. 2. Instruction as to the importance of the universal adoption of prophylactic measures (preferably Credé's method, or the use of a sublimate solution, 1 in 2000, or protargol 20 per cent.) by all lecturers and writers of text-books on midwifery. 3. The appointment of ophthalmic surgeons to maternity institutions, more especially those which provide for attendance of women at their own homes. 4. The provision in all midwifery bags of a drop bottle labeled 'drops for the eyes.' 5. The better training of monthly nurses in the methods of aseptic cleanliness."

**20. Biologic Test for the Blood.**—Linossier denies that the reaction to the serum in the biologic test for the blood is specific, as was assumed at first. Although it is not specific, yet it occurs with greater rapidity and distinctness in the homologous serum, and it is possible, by diluting the blood to be examined, to reduce it to such a point that only the homologous serum has any action upon it. This has generally been done unconsciously in the tests as only minute quantities of the blood were used. The precipitum obtained is smaller in amount the more remote the animals in the scale of living beings from the one whose serum was used to prepare the rabbits for the test. The serum of a rabbit, for example, that had been prepared by intraperitoneal injections of human serum, ascitic fluid or pleuritic effusion, precipitated in a 10 per cent. dilution human, beef, horse, dog, sheep, pig, guinea-pig and fowl serum. But the intensity of the reaction diminished progressively from the first to the last. Another rabbit inoculated with serum from a heifer, precipitated in the same dilution, heifer, horse, sheep, man, pig, dog and fowl serum in progressively diminishing intensity. It precipitated the heifer serum at 1 per 5000, the horse serum at 1 per 300 and human serum at 1 per 50. Linossier noticed that a 1 per 1000 dilution of the blood to be examined gave the reaction with the homologous prepared serum, while no other serum had an influence upon it at this dilution. The fact that this reaction is only apparently and not actually specific does not detract from its medicolegal value if the possibility of error from this source is recognized and measures taken to prevent it by adequate dilution of the blood to be examined. The diluting fluid for the blood should be neutral or slightly alkaline.

**22. Frequency and Prognosis of Actinomycosis in Man.**—Poncet mentions that only 146 cases of actinomycosis in man have been published in France, and these all come from the large medical centers: Paris with 33, and Lyons, his home, 47. At other points the affection is evidently unrecognized, as it is absurd to suppose that it is restricted to the counties with medical schools. Duvau's 1902 thesis is based on the study of 257 cases. The affection proved fatal in those in which deep-seated organs were involved. The mortality has been 2 per cent. for the cutaneous forms; 10 per cent. in the superficial cervico-facial forms; 30 per cent. in the deep temporo-maxillary lesions; 65 per cent. in the abdominal variety; 85 per cent. in the thoraco-pulmonary form and 100 per cent. when in the liver or brain. Poncet has been very successful in treating it with the eurette and drainage, supplemented by large doses of potassium iodid as if for a severe case of syphilis. He commences with 4 gm. and increases to 5 or even 8 gm. with intermissions. He states that this treatment is more effective the more recent the lesion, before mixed infection is established.

**27. Asphyxia of Extremities a Symptom of Renal Insufficiency.**—Ingelrans presents arguments to prove that local asphyxia of the extremities is due to hyperexcitability of the vasomotor system determined by insufficiency of the kidneys. The latter causes the retention of multiple poisons, some of which have a decided vasoconstricting action. When Raynaud's disease and nephritis co-exist, the former is the result of this cause. The nephritis is the primary affection.

**28. Evolution of Instrumentation and Medical Technique and Its Consequences.**—This is the presidential address delivered at the recent French Medical Congress. Lemoine, while reviewing and lauding the wonderful progress in the technique of diagnosing by means of perfected instruments, etc., pointed out

the disadvantages that have resulted. One is the shortening of the distance between the elite of the profession and the empiricists. The physician of the present is inclined to rely too much on his technic and neglect clinical observation. It seems also as if the simplification of instruction had entailed a corresponding loss of effort on the part of the student, so that general culture loses rather than gains by this learning-made-easy. Our predecessors in medicine based their diagnosis on an accumulation of small signs for which they were ever seeking the general connecting links. This pathologic philosophy is the key to many otherwise inexplicable phenomena and its neglect nowadays is a loss. Another of the tendencies of the day is the contempt for the theoretical foundations of medicine. Lectures on this subject are neglected while the students flock to the clinics to observe merely isolated facts. One of the principal factors in curing disease is the faith inspired by the superior intellectuality of the physician. The patient is cured by the physician's words as much as by his remedies, but these words must convey an authority to impress and convince the patient. Any descent from the high classic culture of the past is a menace to this superiority and to the rôle of suggestion expected of the physician. The best means of restoring the prestige of the profession is for the physician to be as far as possible above the level of his contemporaries. He concluded with the prophecy that the reign of the pharmacopeia is almost at an end. The future of therapeutics in the twentieth century is entirely in the line of organic serums, antitoxins and physical measures.

**29. Oil in Abdominal Operations.**—Brennan has been using olive oil for twelve years to prevent the formation of adhesions after abdominal operations. The oil also serves to soothe the existing inflammation and ward off recrudescence and, as it is absorbed, it aids in the nourishment of the patient. He believes that it checks the development of germs. Another advantage of its use is that gauze drains, etc., can be removed later without sticking. The oil is even more effective in this respect than hydrogen dioxide. He sterilizes it under a 15-pound pressure at 250 F. He uses a variable quantity, sometimes as much as 600 c.c. and soaks all the draining wicks in it. Even when he does not drain, he pours a little oil into the abdomen or applies it on a pad, spreading it with the fingers to all the pelvic organs, especially those with raw surfaces or exudation. He believes that it has been the chief factor in the cure of many of his serious cases. It has proved exceptionally beneficial in severe inflammation of the adnexa and appendix, with suppuration and adhesions and in peritonitis.

**31. Dilatation of Esophagus Without Anatomic Stenosis.**—Rosenheim has observed four cases of this so-called idiopathic dilatation of the esophagus. One patient was a man of 55 and treatment of the spasm only aggravated the pre-existent esophagitis. Recovery was rapid when mild local treatment of the inflammation was instituted with rest in bed, hydrotherapy and injection of a 1 per cent. solution of silver nitrate in the upper third of the esophagus and 4 per cent. eucaïn below. The patient was dismissed in five weeks entirely relieved of his troubles. Another patient was much benefited by forcible dilatation with sounds. The reaction of the cardia to the contact of the sound is not a reliable criterion to determine its functional capacity.

**33. Streptococcus Toxin.**—Marmorek announces that all streptococci, whatever their origin, produce the same toxin. It belongs to the group of diastases which succumb to a temperature of 70 C. The serum derived after inoculation with one kind of streptococcus is effective against the toxin elaborated by all the other varieties.

**43. Agglutination of Dysentery Bacillus.**—Foulerton found that the agglutinative reaction with the bacillus dysenteriae was the same with serum from home cases of dysentery as with that from cases occurring abroad. He found the test positive in six out of seven at a dilution of 1 to 40 and even 1 to 100 in some instances. There was no agglutination with the typhoid bacillus.

**51. Duration of Life of Tubercle Bacilli in Cheese.**—Har-

rison reports that no tubercle bacilli can be found alive in Canadian Cheddar cheese after ten weeks at the utmost.

**63. Hemoglobinuria.**—Stempel reviews 151 articles on this subject with 14 additional on the infectious and 31 on the toxic variety. There has been scarcely a single case of paroxysmal hemoglobinuria reported which proved fatal or in which there were evidences of any permanent injury of the kidneys. But the infectious and toxic varieties were almost universally fatal. This was due in part to the more complete obstruction of the tubules with masses of hemoglobin and the resulting uremia, and in part to the frequently associated acute nephritis. The elimination of albumin and tube casts may persist for weeks in the infectious and toxic forms. The regeneration of the blood proceeds much more rapidly and perfectly in the paroxysmal variety. Toxic hemoglobinuria has been induced by hemoglobin itself, as in cases of extensive burns or freezing in which large amounts of the reds were destroyed. This fact has been confirmed experimentally and in practice, as after the transfusion of lamb's blood, etc. Other substances liable to induce hemoglobinuria are snake venom, the mushroom *helvella esculentia* under certain conditions, sulphuric, hydrochloric, oxalic and pyrogallie acid and anilin oil. Among the medicines which have produced hemoglobinuria is potassium chlorate. Stempel observed a fatal case in a robust young person after ingestion by mistake of a solution of this substance recommended for a gargle. An infant with thrush also died of hemoglobinuria in a few days after its mouth had been wiped out several times with the powder. Carbolic acid and the allied benzol combinations are also liable to induce hemoglobinuria as the principal symptom of intoxication, both when ingested or applied to a large superficial area. Schellenberg has reported 30 cases of toxic hemoglobinuria from the use of a 10 per cent. emulsion of glycerin and iodoform. In the mild cases the urine was reddish for four hours, with slightly accelerated pulse and temperature. In the severe forms the symptoms are more intense and may entail anuria and death, with indications of recent inflammation in the kidneys. The toxic dose he found to be 10 gm. for children and for adults 20 to 25 gm. The walls of an abscess cavity absorb very slowly and in very small amounts, but absorption is rapid in the serous membranes of a joint and on the surface of a recent wound. Various gases are able to induce hemoglobinuria, sewer gas and the products of the consumption of illuminating gas. A gas stove without outlet for the products of combustion was installed in Stempel's operating room, and he found that he was having hemoglobinuria which was finally traced to this source. Examination of the air over the stove showed the presence of acetylene gas. He warns against the use of illuminating gas in an operating room, among other reasons on account of its possible union with chloroform to form a toxic combination. Two cases have been reported of hemoglobinuria consecutive to the reabsorption of large intra-abdominal hemorrhages. In regard to quinin, it seems to be established that one form of hemoglobinuria in malaria can only be cured by quinin, while another form is directly induced by the quinin. Koch recommends copious drinking of fluids during a malarial attack when no parasites are to be found in the blood, in order to prevent the formation of infarcts of hemoglobin. If the parasites are present in the blood he advises very small amounts of quinin or better still to substitute it with 1 gm. a day of methylene blue.

**64. Healed Bullet Wounds of the Head.**—Von Bergmann describes some cases to sustain his opinion that it is better to refrain from trying to extract the bullet when it is of the ordinary 5 to 9 mm. caliber from a small weapon. The wound soon heals if kept aseptic, and it is possible for even very severe symptoms to subside in a short time. On the other hand, it is sometimes impossible to locate the bullet, even with the aid of skiagraphy, and the traumatism resulting from the search for it is more injurious than the effect of the bullet left to itself.

**65. Examining for Appendicitis.**—Rose reiterates his conviction, which experience has more and more confirmed, that an otherwise healthy person should not and does not die of ap-

pendicitis unless operation is deferred until too late. The indications are the same as for an incarcerated hernia. He is amazed at the number of instances in which the appendicitis was unrecognized, as in a case he describes at length which was reported as a fatal traumatic abdominal affection. The autopsy disclosed recent, acute diphtheritic appendicitis and diffuse peritonitis without adhesions. This violent form of appendicitis is usually fatal in less than eight days, before there is time for a palpable tumor to develop, and before the appendix has perforated. The toxins generated in the appendix are able to penetrate its walls and induce the peritonitis in such cases. Many persons have succumbed to this affection, which has been erroneously designated peritonitis, disregarding the primary focus of infection in the appendix with its apparently intact walls. The intestines must be emptied before it is possible to palpate them understandingly. Just as an ulcer on the foot requires cleansing and removal of the crusts before disinfection is possible, an ulcerating intestine should be freed from stagnating fecal matters by small doses of castor oil or, in case of typhoid, large doses of calomel. After the intestines are empty and the patient restricted to a milk diet, the characteristic painful point must be sought with gentle pressure, regardless of the absence of spontaneous pain. The more systematically and scrupulously this is done, the less frequent will become the cases of "latent" or "masked" appendicitis. In the very violent forms, the slightest touch to the specific painful point causes intense pain, and the earlier this is discovered the better the chance for successful surgery. The appendix lies in such a sheltered spot that this characteristic painful point does not come in contact with anything external that elicits the pain, and thus it is ignored unless carefully sought or some traumatism occurs. This explains why appendicitis in many cases is referred to a traumatism. The contusion elicited the characteristic pain for the first time, but it could have been produced before if it had been sought. The simultaneous appearance of continuous vomiting and slight fever should be the signal for operating without waiting for the development of dulness or a perityphlitic tumor. The dangers of appendicitis are still underestimated.

**66. Transplantation of the Testicle in the Scrotum.**—This article, by the late Professor Wolff, is based on his experience in five cases, the patients 3, 4, 10, 18 and 20 years old. The transplantation of the testicle is as effective as its extirpation in the treatment of cryptorchidism, while the moral effect on the patient is far better. In his five cases, although the testicle was usually higher than normal after it was transplanted, there was no inflammation even during the stress of military service. There is no case on record, he states, in which a malignant neoplasm developed in the transplanted testicle. It is much more liable to this in its ectopic position. The technic of transplantation from the inguinal region is extremely simple. In all his cases the testicle increased in size after its removal, although it never became as large as its mate. Retention of the testicle should be treated in this way without waiting for disturbances to develop, except in the cases in which spontaneous descent is still possible, aided perhaps by manipulative measures. Extirpation should be reserved for suspected cancerous degeneration. The same rules apply to the testicle retained in the abdomen or inguinal region as to a normal testicle, and it should not be sacrificed any sooner.

**67. Surgical Treatment of Ascites in Case of Cirrhosis.**—Kümmell doubts whether the establishment of a collateral circulation in case of cirrhosis of the liver will ever result in a complete cure. But it relieves the patient of the most distressing symptom, the ascites, and reduces the size of the liver and spleen and thus enables him to resume his occupation for a longer or shorter time. In one of his seven cases thus treated the operation was done unconsciously during a laparotomy for the relief of an assumed hydatid cyst. The omentum kept protruding through the wound in spite of all efforts to reduce it and was finally sutured in the wound. This was in 1887. When the patient was seen again three years later, there was a network of congested veins around the wound. The

ascites and liver tumor had vanished and the patient had been permanently restored to business. This inexplicable success was not comprehended until Talma's recent announcements of the benefits to be derived in such cases from fastening the omentum to the abdominal wall to establish collateral circulation. The Talma operation was combined with herniotomy in another case, curing the patient of the ascites at the same time as of the liver tumefaction. He died of an intercurrent erysipelas five days later, and the abdomen was found free from ascites. One of the most successful operations was on a man of 54, who was in an almost moribund condition when operated on. The increasing ascites rendered the reduction of an old hernia impossible, and the liver extended nearly to the rim of the pelvis. There was occasional delirium. The operation was followed by threatening collapse the seventh day and a brownish ascitic fluid trickled from the wound. The general health began to improve the fourteenth day and the patient could get up the thirtieth, and was dismissed ready for work twelve weeks after the intervention.

**68. Cure of Osteomalacia in a Nullipara by Castration.**—Holländer adds another to the three cases of osteomalacia in nulliparæ cured by castration. The pains disappeared immediately after the operation and the patient can now take long walks. The osteomalacia was not so pronounced as in the puerperal form, but the gait and pains were characteristic. The patient, aged 36, had been treated for nearly ten years for supposed rheumatism. The diagnosis was confirmed by radioscopy.

**69. The Vibrating Sound.**—Laskowski attributes the beneficial effects of the sound in urethral affections to the massage which it induces. He has succeeded in materially increasing the amount of massage by constructing a sound on the principle of vibration instruments. After numerous trials of various devices he recommends a large metal sound fitted into the rolled end of a wide metal spring, wider and stronger than a watch spring. The end of the spring holding the sound is screwed flat between two narrow metal plates fastened together with two thumb screws and nuts. The sound is inserted in the urethra and slight blows are struck on the projecting coil of the spring with a padded mallet. The vibration thus induced is not disagreeable and is not followed by any inconveniences. It can be repeated every second or third day or even daily if necessary. The sound used is as large as can be introduced without pain, as the walls of the urethra respond better to the vibration when they are stretched. The effect was favorable in cases of over-stimulation as well as in those of relaxation. Abnormal sensations in the urethra were banished. Incontinence of non-central origin was cured, and the effect was most excellent, or at least satisfactory in all cases of sexual neurasthenia, phosphaturia and prostaticorrhea. Recent inflammation and the presence of gonococci are contra-indications. At first the suppurative and filaments seem to increase, but this is merely the cleansing effect of the procedure, and is soon followed by thinner secretions and decreasing numbers of filaments. (See cut in original.)

**71. Clinical Importance of Seborrhæic Eczema.**—Bonne emphasizes that the coincidence of Unna's eczema seborrhæicum with adenoids and the lymphatic constitution is not casual, but that the former is the causal basis of this constitution. This variety of eczema is also directly related to the uric acid diathesis and certain forms of asthma and possibly, in connection with the uric acid diathesis, favors the development of carcinoma. The eczema is in every case the direct cause of the so-called scrofulous tendency. Infants should be protected against infection from seborrhæic mothers, nurses and attendants, and strengthened by hygienic measures of all kinds and moderation in eating. Adenoids and enlarged glands should be removed without delay. All manifestations of eczema and of catarrh of the mucous membranes should be thoroughly treated. These measures should be supplemented by the occasional internal use of far-water, which he considers the best of all remedies for the tendency to eczema. In his experience, every patient with carcinoma was or had been affected with

eczema, and he is convinced that further research will confirm this connection between them and indicate new lines for prophylaxis.

**73. Surgical Treatment of Puerperal Pyemia.**—Trendelenburg refers only to that form of pyemia of uterine origin due exclusively or principally to septic thrombosis of the veins of the uterus. The success of operative treatment of otitic pyemia, by evacuating the sinus transversus and ligating the inferior jugular vein, inspired him to attempt a similar procedure in puerperal pyemia. The conditions are much less favorable in the latter as the vein trunks are more numerous and less accessible, but it is possible to overcome all difficulties and operate outside of the peritoneum. The first chill in pyemia is the signal that the enemy is installed and has opened fire. If no other cause can be assigned for the chill and a second follows, it is more than likely to be due to pyemia and operative intervention is indicated at once. Bimanual investigation will reveal on which side the thrombosis is located or whether it is bilateral. In the autopsies of 21 cases the thrombosis was single in only 7, and on both sides in 14. In 5 it was limited to the veins of the parametrium and in 9 the vein trunks were involved. The uterine was affected twice as often as the ovarian. It is therefore advisable in doubtful cases to ligate the uterine on both sides, ligating the ovarian later if need be. Even in long-established cases the ligation of these veins is liable to have a decidedly favorable effect on the infection. Trendelenburg reports one case in which a vi-par, 35 years of age, unmistakably owed her life to the ligating of the uterine vein on the right side, followed by that of the ovarian. Fever and daily chills, from three-quarters to two hours in length, followed an abortion at three months. A tumor the size of a small egg, painful on pressure, was discovered in the right parametrium. It was evacuated through the vagina after a futile exploratory laparotomy on the mistaken diagnosis of a pyosalpinx. The abscess was in the broad ligament and the pus contained streptococci. The chills continued, one or two a day, two hours long, and the twenty-third day after the first operation the right uterine vein was divided between two ligatures just above its junction with the external iliac. The vein below was discolored, but there were no evidences of thrombosis. The wound above Poupert's ligament was partially closed and drained with gauze. There were no further chills during the next ten days, and the patient felt subjectively much better. The chills then recurred, at first short, but gradually increasing in length and frequency and the strength rapidly declined. One month after the first intervention the ovarian vein was exposed through an incision on a level with the lower pole of the kidney, the incision carried downward from the tip of the eleventh rib. About 5 cm. of the vein was resected. The lower portion was obstructed with a grayish-yellow thrombus, while the upper portion was free. The thrombus contained quantities of cocci. There were no further chills; merely an occasional chilly feeling until the sixteenth day, when a metastatic abscess in the right scapular region was opened, after which the patient recovered her health and weight, although irregular fever persisted for a long time. She was dismissed in satisfactory condition December 18. The abortion occurred, August 31. This is the first case of puerperal pyemia cured by ligating the veins. It suggests that prompt surgical intervention may prove effective even in the acute form.

**74. Regeneration of Long Bones in Osteomyelitis and Tuberculosis.**—Berndt observed in all of his 40 cases of osteomyelitis and tuberculosis during the last five years that the primary focus was in the bone marrow. After evacuation of the surrounding pus, this small focus generally healed spontaneously. In the cases in which the severe symptoms persisted after evacuation, and amputation seemed inevitable, he succeeded in curing a number by complete extirpation of the bone affected. He found that in every instance new bone tissue formed, thus preserving a good limb, only slightly shorter than normal. In the first patient the entire tibia except the lower epiphysis was involved in the osteomyelitic process. The pus had perforated into the knee. One year after the operation the

boy, now 8, is in perfect health. The leg is 4 cm. shorter than the other. In a girl of 15 the entire lower half of the femur was removed. It regenerated slightly in excess of normal. The other cases were equally satisfactory. In one the clavicle was removed and regenerated, in another the entire humerus, on account of a recurring tuberculous lesion. The indispensable conditions are the retention of the periosteum and the non-closure of the wound. The periosteum requires a certain irritation to stimulate it to bone formation. The bone did not regenerate in the cases in which the wound was closed at once. Radiographs are appended showing the almost normal aspect of the bones.

**76. Urethral Fever Due to Penetration of Bacteria into Blood.**—This communication from Wiesinger's service at Hamburg describes the particulars of three cases of fever from a stricture in the urethra. Catheterization was probably responsible for the penetration of the bacteria into the blood in some. Lengthwise erosions were noted in one case. In others, the efforts at urination probably forced the urine accumulated above the stricture directly into the tissues and thence into the blood. The penetration of the germs into the blood causes the chill and urethral fever in a certain proportion of cases. The germs may vanish from the blood and all symptoms rapidly disappear, or they may lead to sepsis or septic endocarditis. The milder variety of urethral fever is probably due to the invasion of non-pathogenic germs. Lenhartz has reported that out of 38 cases of malignant endocarditis in his experience, 7 had been preceded by catheterization or other manipulation of the urinary passages. In one of the rapidly-recovering personal cases described, the proteus was found in enormous quantities in the blood and 60 colonies of streptococci were derived from 15 c.c. of blood in the other. He distributes this amount of blood in 6 tubes of liquefied agar, from which he makes a plate culture. Thousands of colonies of staphylococci and colon bacilli were derived from 15 c.c. of blood, as well as from the urine of a third patient. The first chill and fever were followed by comparative recovery for twelve days, after which the symptoms recurred with greater intensity and the staphylococcus was found in pure cultures. The autopsy disclosed a septic endocarditis of about a week's duration, corresponding to the severer symptoms. The patient had been catheterized three times in the course of the bacteriemia. His condition did not permit surgical intervention. The article concludes with the warning that dilation of strictures requires the most extreme care. Lenhartz's experience confirms the dangers of the procedure, as also a case of sepsis after catheterization described in the *Wien. Klin. Woch.*, 1896, 18. The bladder should be disinfected beforehand, if possible, or at least afterward. Bougies with guides are safer than others. In severe cystitis a permanent catheter is perhaps advisable. Salol or urotropin should be given immediately after the dilation and, if possible, beforehand. By observing these precautions Wiesinger has reduced the number of cases of urethral fever in his service to 2 out of 18 patients with strictures submitted to multiple catheterization, while in 1900 he had 8 cases of it in 6 out of 16 patients. The patients have usually been more or less infected before reaching the hospital. The practical conclusions from his experience are that when a violent chill follows careful catheterization or the blood contains bacteria, the stricture should be excised at once without delay, afterward reuniting the anterior wall of the urethra according to König.

**77. Insufficient Tension of the Muscles and Its Treatment.**—Lange reiterates that a lack of elasticity or excess of length is responsible for insufficient function of muscles and tendons in many cases in which it is erroneously referred to other causes. He reports a number of cases treated on this principle by shortening the muscle. In one patient bilateral pes calcaneus, existing for twelve years after Little's disease, was completely corrected by taking a tuck in the tendo Achillis. The threads suppurated out in one foot, but the desired result was obtained in both. The gastrocnemius in this case behaved as if paralyzed, while in fact the trouble was merely the excessive length of the tendon. He usually shortens a tendon by

weaving a silk thread lengthwise through it and back again in parallel stitches. When the thread is drawn taut and the ends tied, the tendon is shortened and the straight edge becomes wavy. Lange advocates this method for the treatment of traumatism or deformities of tendons or muscles. Intervention to shorten unduly long muscles promises as excellent results as tenotomy for unduly short ones.

**81. Traumatic Heart Affections.**—Ecklentz has collected and reviews 18 cases of rupture of the heart from a contusion and 5 of tissue degeneration from the same cause. He reports six cases of traumatic affections of the heart personally observed. One patient was a woman of 60, and an old caseous tubercular focus was found in the lung at the autopsy. The traumatism had evidently crushed it and released the bacilli which had then settled on the pericardium and had induced a fresh tubercular pericarditis, fatal in less than ten weeks. In another case a febrile acute endocarditis developed in a young person after contusion of the thorax. He has witnessed three cases of chronic endocarditis, the patients being a man of 30 and boys of 12 and 17. The aortic valve was lacerated in one patient. In all his personal cases the injury had been caused by a passing wagon.

**83. Intestinal Putrefaction with Varying Diet.**—Backman reports tests which confirm the facts that the carbohydrates do not seem to have much influence on putrefaction in intestines. It is proportionate to the amount of albumin in the food. An exclusive or predominant milk diet materially diminishes the putrefactive processes.

**84. Gastric Achylia.**—Kuttner deprecates the separation of gastric achylia from the ordinary disturbances in secretion in the course of catarrhal or atrophic processes in the gastric mucosa. If there is a special nervous foundation for the condition we have no means yet of proving it.

**86. Influence of Antipyresis on Agglutinative Power of the Blood.**—Beniasch attributes the discredit into which the antipyretics have fallen of late, as merely the reaction to the exaggerated enthusiasm of twenty years ago. If the febrile temperature is, as some assert, a necessary weapon in the struggle of the organism with the infection, it is a two-edged sword, as it entails a series of most unwelcome phenomena. It is subjectively experienced as a very severe symptom, and objectively it induces a number of threatening manifestations on the part of other organs, especially of the heart and nervous system. The artificial lowering of the temperature by the antipyretics did not diminish the agglutinating power of the blood in the twenty-three cases of typhoid fever examined. If any effect was perceptible it seemed to be rather an increase.

**89. Ocular and Visual Disturbances Induced by Tobacco.**—Santos Fernandez announces that disturbances of this kind are comparatively rare in Havana, notwithstanding the widespread use of tobacco. Conjunctivitis produced by floating particles in tobacco factories is extremely rare and mild. There are 150 tobacco factories and they employ between 12,000 and 13,000 employees, but the buildings are not constructed so airtight as in colder climates, and Havana tobacco, he adds, contains only 2 or 3 per cent. nicotin, while French and American tobacco has 8 to 9 per cent. This is probably the reason why nicotin amblyopia is so much less frequent than in Europe, notwithstanding the incessant smoking. His experience includes 36,000 inscribed patients and 200,000 consultations in his ophthalmologic practice. Asthenopia is more frequent, and he also mentions the predominance of hypermetropia in Cuba in contrast to other countries in which myopia generally prevails.

**93. Antithermic Therapeutics.**—Maragliano calls attention to the individual thermic resistance of each patient, that is, the resistance which his organism opposes to the means we apply to reduce the fever. It varies with the age, sex, etc., and at different periods of the disease in the same subject, but it is an important factor in the result attained by therapeutic and physical measures. The thermic resistance of each patient must be determined in order to secure the best results from baths in the treatment of the fever. The first bath should be of moder-

ate temperature and its influence on the rectal temperature carefully noted. This will establish a standard for succeeding baths, raising or lowering the temperature as indicated by the reaction to the first bath. If the temperature falls below 37 C., the water was too cold; if the drop is less than one or three degrees C. the water was not cold enough. The temperature of the bath should thus be adjusted to the thermic resistance of the patient as determined by the first bath at a moderate temperature. The thermic resistance is always most marked in erysipelas and typhoid fever. Attempts to regulate the temperature of the bath by the peripheral temperature of the patient, he considers rank empiricism. As the aim of the bath is to promote the elimination of heat, this should be favored as much as possible by stimulating the cutaneous circulation by friction during and after the bath, and by the administration of a certain amount of alcohol before the bath. This has the property of stimulating the cutaneous circulation, while at the same time it induces a slight degree of vasomotor paralysis. Antipyrin has practically the same effect, but alcohol is not so dangerous a poison for the protoplasm as antipyrin. The patient should be covered warmly with blankets after the bath to promote still further the cutaneous circulation, unless it is already active and the skin red, when the blankets can be dispensed with. It is advisable to supplement the action of the bath by a cloth tucked around the trunk from the inguinal to the axillary region, kept moistened with cold water. In case hydrotherapeutic measures are impracticable and the physician has to use chemicals, quinin then ranks first. Its action is not apparent before eight hours, but it is equally effective in all kinds of fevers. The only problem is to proportion the dose to the disease. When more rapid action is desired pyramidon, antipyrin and phenacetin are the least harmful of the chemical group.

**94. Pathogenesis of Exophthalmic Goitre.**—Tedeschi has established that a lesion of the restiform body is able to induce in rabbits and dogs not only exophthalmus and tachycardia, but a generalized tremor, polyuria, glycosuria and salivation. This occurred invariably in his experimental research when the lesion was in the anterior portion of the restiform body, directly behind the auditory tubercle.

**98. Inoculation of Vaccine from Calf to Calf.**—Umeno is chief of the official vaccine laboratory of Japan. He became convinced that the reason for the failure of calf-to-calf inoculation was that the virus was used in too concentrated a form. By diluting it to one-twelfth he found that it could be passed through fifty calves in turn, gaining instead of losing in effectiveness. He inoculates an area of 2.5 sq. cm. to the kilogram of the animal, and the pustule matures after the same interval as when humanized lymph is used.

## Queries and Minor Notes.

### SHOULD THE PHYSICIAN CHARGE?

LAFAYETTE, IND., April 24, 1902.

*To the Editor:*—Suppose the unmarried daughter (over age) of a physician long since dead, and who is worth considerable property is treated by a physician and dies, is the doctor justified in presenting a bill against her estate? Should not the doctor charge for treating the daughter of a deceased doctor who has married a man outside the medical profession?

SUBSCRIBER.

ANS.—Yes, in both cases.

### New Patents.

Patents of interest to physicians, April 8 and 15:

- 697,336. Tongue scraper. Ida Hagerty, Austin, Texas.
- 697,209. Device for facilitating taking pills. Benno Koppenhagen, Untereunbrunn, Germany.
- 697,412. Syringe nozzle. Robert L. McMurran, Portsmouth, Va.
- 697,164. Abdominal support. Isaac E. Palmer, Middletown, Conn.
- 697,181. Instrument for cooling or for warming internal portions of the human body. Roy E. Smith, Portland, Ore.
- 697,117. Pocket inhaler. Harry J. Valentine, Hempstead, N. Y.
- 697,825. Nursery milk warmer and night lamp. John M. Flisk, Malone, N. Y.
- 697,677. Shield for vaccinations, etc. John E. Lee, Conshohocken, Pa.
- 697,731. Making lithophone. Jens P. Lihme, Cleveland, Ohio.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., April 10 to 16, 1902, inclusive:

George M. Decker, contract dental surgeon, leave of absence for fifteen days, to take effect on his arrival in the United States.

Basil H. Dutcher, captain and asst.-surgeon, U. S. A., member of a board at West Point, N. Y., to examine the cadets of the graduating class at the U. S. Military Academy.

Douglas F. Duval, lieutenant and asst.-surgeon, U. S. A., is relieved from duty on the transport *Thomas* and from further duty in the Division of the Philippines; on arrival of the transport at San Francisco, Cal., he will report for duty at Fort Williams, Me.

Charles L. Helzmann, lieutenant-col. and deputy surgeon-general, relieved from duty as chief surgeon, Division of the Philippines, to take effect about June 1, 1902, when he will proceed to San Francisco, Cal., and report by telegraph to the Adjutant-General of the Army for orders.

Walter D. McCaw, major and surgeon, U. S. A., president of a board at West Point, N. Y., to examine members of the graduating class at the U. S. Military Academy.

James E. Mead, captain and asst.-surgeon, Vols., leave of absence for one month granted, taking effect from April 10, 1902.

Alexander N. Stark, captain and asst.-surgeon, U. S. A., member of a board at West Point, N. Y., to examine cadets of the graduating class at the U. S. Military Academy.

Albert E. Truby, lieutenant and asst.-surgeon, U. S. A., on his arrival from Cuba to report for duty at Fort Wadsworth, N. Y.

Henry S. Turrill, major and surgeon, U. S. A., on his arrival at San Francisco, Cal., to report at Omaha, Neb., for duty as chief surgeon of the Department of the Missouri.

Sanford H. Wadhams, lieutenant and asst.-surgeon, U. S. A., leave of absence for one month granted.

Charles K. Winne, lieutenant-col. and deputy surgeon-general, relieved from duty as chief surgeon, Department of the Missouri, to take effect April 30, 1902, and to proceed to his home to await retirement from active service.

During the week boards were appointed to meet at certain military stations on May 1, 1902, for the examination of such candidates for the Military Academy as might be authorized to appear before them. The following medical officers were constituted members of these boards:

At Fort Warren, Mass., George W. Mathews, lieutenant and asst.-surgeon. At Fort Ethan Allen, Vt., Charles B. Mittelstaedt, contract surgeon. At Fort Columbus, N. Y., William H. Corbusier, major and surgeon, and Eugene H. Hartnett, lieutenant and asst.-surgeon. At Fort Porter, N. Y., William P. Kendall, major and surgeon. At Fort McHenry, Md., William F. Lippitt, Jr., captain and asst.-surgeon. At Fort Thomas, Ky., William W. Gray, major and surgeon, and Francis M. Wall, contract surgeon. At Fort McPherson, Ga., William D. Crosby, major and surgeon. At Fort Sheridan, Ill., Francis J. Ives, major and surgeon, and Charles F. Smith, contract surgeon. At Jefferson Barracks, Mo., Francis A. Winter, captain and asst.-surgeon, and Alva R. Hull, contract surgeon. At Fort Logan H. Roots, Ark., Carle E. Bentley, contract surgeon. At Jackson Barracks, La., Henry C. Fisher, captain and asst.-surgeon. At Fort Snelling, Minn., Elbert E. Persons, lieutenant and asst.-surgeon. At Fort Leavenworth, Kan., Henry P. Birmingham, major and surgeon, and David Baker, lieutenant and asst.-surgeon. At Fort Sam Houston, Tex., Charles F. Mason, major and surgeon. At Fort Logan, Colo., John L. Shepard, contract surgeon. At the Presidio of San Francisco, Cal., Henry S. Greenleaf, lieutenant and asst.-surgeon, and Milton E. Lando, lieutenant and asst.-surgeon.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending April 19, 1902:

Asst.-Surgeon W. L. Bell, ordered to Pocatello, Idaho, on recruiting duty.

Asst.-Surgeon R. M. Young, detached from the *Rainbow* and ordered to the Cavite Naval Station.

Dr. F. M. Munson, appointed asst.-surgeon, April 5.

P. A. Surgeon M. S. Guest, detached from the Cavite Naval Station and ordered to the *New Orleans*.

P. A. Surgeon H. D. Wilson, ordered to duty with the Marine brigade, Philippine Islands.

Asst.-Surgeon R. C. Holcombe, ordered to proceed home via *Manila*.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended April 17, 1902:

Surgeon C. E. Banks, granted leave of absence for five days from April 14.

Asst.-Surgeon M. J. White, to proceed to Reno, Nev., for special temporary duty.

A. A. Surgeon B. W. Goldsboro, granted leave of absence for seven days.

A. A. Surgeon R. T. Walker, granted leave of absence for 18 days from May 1.

#### BOARDS CONVENED.

Board convened at Baltimore, Md., to inspect steam tug *Neptune*. Detail for the Board: P. A. Surgeon H. D. Geddings, M.-H. S., and Chief Engineer H. W. Spear, R.C.S.

Board convened at the Bureau April 14, for the physical examination of candidates for appointment to grade of second assistant engineer, R.C.S. Detail for the Board: Surgeon L. L. Williams, chairman, and Asst.-Surgeon S. B. Grubbs, recorder.

Board convened at New Orleans, La., April 14, for physical examination of an officer of the Revenue Cutter Service. Detail for the Board: P. A. Surgeon C. P. Wertenbaker, Chairman, and Asst.-Surgeon J. W. Scherschewsky, recorder.

Board convened at Marine Hospital Office, San Francisco, Cal., April 21, to examine officers of Revenue Cutter Service. Detail for the Board: P. A. Surgeon W. G. Stimpson, chairman, and P. A. Surgeon H. S. Cumming, recorder.

Board convened at Marine Hospital, Port Townsend, Wash., April 21, to examine an officer of the Revenue Cutter Service. Detail for the Board: P. A. Surgeon C. H. Gardner, chairman, and Asst.-Surgeon M. H. Foster, recorder.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended April 18, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, March 29-April 5, 9 cases; San Francisco, March 30-April 6, 9 cases.

Colorado: Denver, March 28-April 4, 8 cases.

Illinois: April 5-12, Chicago, 14 cases; Freeport, 1 case.

Indiana: April 5-12, Evansville, 5 cases; Indianapolis, 13 cases; Terre Haute, 2 cases.

Kansas: Wichita, March 29-April 12, 9 cases; one case imported from Oklahoma.

Kentucky: Covington, April 6-13, 7 cases.

Louisiana: April 5-12, New Orleans, 1 case imported from Mississippi; Shreveport, 7 cases.

Maine: Portland, April 5-12, 9 cases, 1 death.

Maryland: Baltimore, April 5-12, 1 case.

Massachusetts: April 5-12, Boston, 13 cases, 3 deaths; Brockton, 2 cases; Cambridge, 2 cases; Everett, 1 case; Lawrence, 1 death; Lowell, 2 cases; Malden, 1 case; New Bedford, 1 case; Quincy, 2 deaths; Somerville, 3 cases.

Michigan: April 5-12, Detroit, 18 cases; Ludington, 19 cases.

Minnesota: Winona, April 5-12, 2 cases.

Missouri: St. Louis, March 30-April 6, 50 cases.

Montana: Butte, March 30-April 13, 7 cases.

Nebraska: Omaha, April 5-12, 24 cases.

New Jersey: Camden, April 5-12, 4 cases; Hudson County, including Jersey City, March 30-April 6, 30 cases, 9 deaths; Jersey City, March 30-April 6, 24 cases; Newark, April 5-12, 42 cases, 10 deaths.

New York: New York, April 5-12, 66 cases, 12 deaths.

Ohio: Cincinnati, April 4-11, 16 cases; Dayton, April 5-12, 1 case; Hamilton, March 9-April 5, 5 cases; Toledo, April 5-12, 2 cases; Youngstown, April 5-12, 1 case.

Pennsylvania: Altoona, April 5-12, 2 cases; Johnstown, April 5-12, 1 case; Philadelphia, April 5-12, 35 cases, 4 deaths; Pittsburgh, March 29-April 12, 10 cases; York, March 5-April 5, 7 cases, 3 deaths.

Rhode Island: Providence, April 5-12, 5 cases.

South Carolina: Greenville, March 29-April 5, 4 cases.

South Dakota: Sioux Falls, April 5-12, 3 cases.

Tennessee: Memphis, April 5-12, 8 cases.

Utah: Ogden, March 1-31, 4 cases; Salt Lake City, April 5-12, 1 case.

Washington: Tacoma, March 30-April 6, 7 cases.

Wisconsin: Green Bay, April 5-12, 7 cases; Milwaukee, March 29-April 5, 1 case.

#### SMALLPOX—INSULAR.

Porto Rico: March 1-22, Arecibo, 61 cases; Ciales, 6 cases; Fajardo, 1 case; Humacao, 1 case; Ponce, 12 cases; San Juan, 6 cases.

#### SMALLPOX—FOREIGN.

Austria: Prague, March 15-29, 13 cases.

Barbados: March 30, 10 cases.

Belgium: Antwerp, March 22-29, 10 cases, 4 deaths.

Brazil: Pernambuco, Feb. 14-28, 27 cases, 27 deaths.

Canada: Belleville, March 31-April 7, 1 case; Quebec, March 29-April 12, 48 cases, 1 death.

France: Paris, March 22-29, 1 death; Rheims, March 16-30, 51 cases, 4 deaths.

Great Britain: Birmingham, March 22-29, 1 case; Dundee, March 22-29, 1 case; Glasgow, March 28-April 4, 13 cases; Leeds, March 22-29, 2 cases; Liverpool, March 22-29, 4 cases, 1 death; London, March 22-29, 389 cases, 61 deaths; North Shields, March 15-22, 7 cases; Sheffield, March 15-22, 1 case; South Shields, March 22-29, 2 cases.

India: Bombay, March 4-18, 19 deaths; Calcutta, March 1-15, 14 cases; Karachi, March 2-16, 8 cases, 6 deaths; Madras, March 8-14, 4 deaths.

Italy: Caserta, March 24, many cases; Milan, Feb. 1-28, 5 cases, 3 deaths; Naples, March 15-22, 7 cases, 1 death; Palermo, March 15-29, 37 cases, 4 deaths; Santa Maria Capuavetere, March 24, many cases.

Mexico: Mexico, March 23-30, 2 cases, 3 deaths.

Netherlands: Rotterdam, March 22-29, 2 cases.

Russia: Moscow, March 15-22, 18 cases, 3 deaths; Odessa, March 22-29, 2 cases, 1 death; St. Petersburg, March 15-29, 14 cases.

Switzerland: Geneva, March 8-15, 1 case.

#### YELLOW FEVER.

Dutch Guiana: Paramaribo, Feb. 1-28, 7 deaths.

French Guiana: March 31, Mana, infected; St. Jean, infected; St. Laurent, infected.

#### CHOLERA.

China: Honan, April 10, epidemic; Hongkong, March 4, 1 case.

India: Bombay, March 4-18, 41 deaths; Calcutta, March 1-15, 258 deaths.

Turkey in Asia: Djiddah, to March 27, 38 deaths; Mecca, to March 27, 788 deaths; Medina, to March 27, 381 deaths; Rebuk, to March 27, 1 death.

#### PLAQUE—INSULAR.

Philippine Islands: Manila, Feb. 1-22, 2 cases, 2 deaths.

#### PLAQUE—FOREIGN.

China: Shantung, Feb. 10, 300 deaths; Yeung Kong, Feb. 10, prevalent.

India: Bombay, March 2-18, 1635 deaths; Calcutta, March 1-15, 963 deaths; Karachi, March 2-16, 167 cases, 147 deaths; Madras, March 8-14, 1 death.

### LESIONS OF THE CONUS MEDULLARIS AND CAUDA EQUINA.

A CONTRIBUTION TO THE STUDY OF SPINAL LOCALIZATION.

BERTRAM W. SIPPY, M.D.

ASSISTANT PROFESSOR OF MEDICINE, RUSH MEDICAL COLLEGE.  
CHICAGO.

It is only within the past few years that lesions of the conus medullaris and cauda equina have attracted the attention of medical writers. In 1895 Raymond collected 29 cases of spinal disease, in which either one or the other of these structures were involved. Since then Clemens, Schiff, Church, Koster, Mueller, Sachs and a few others have reported similar conditions. The symptoms produced by disease of the conus medullaris and cauda equina are well defined and, as a rule, easy of recognition. Experience shows, however, that unless one has learned to search directly for them, they may be readily overlooked. My chief aim in presenting this paper is to further the recognition of the clinical picture indicative of disease of these important structures.

The conus medullaris occupies a position in the spinal canal directly behind the first lumbar vertebra. Upon exposing the spinal cord, the conus is completely hidden from view by a mass of firm and coarse fibers, constituting the beginning of the cauda equina. Anatomically, its upper limit has not been accurately defined. Text-books on anatomy and neurology, if they refer to the conus medullaris at all, usually describe it as that conical portion of the spinal cord below the lumbar enlargement. Clinicians, in describing cases, have pleased their own fancy relative to its boundaries. Thus, Bräutigam places its upper limit at the lower part of the lumbar enlargement. Valentini and others have described, as conus lesions, disease involving the whole sacral cord. Raymond, Müller and others who have written on the subject recently are inclined to limit the conus medullaris to that portion of the cord represented by the third, fourth and fifth sacral and the coccygeal segments. The recent studies of Müller relative to the histology of the lower end of the spinal cord appear to justify such an anatomical limitation.

The clinical picture produced by lesions of the conus medullaris thus anatomically restricted is characterized by well-defined sensory and motor disturbances. Sensation is impaired in an area symmetrically distributed, which involves the integument of the penis, scrotum, perineum, anus, inner aspect of the buttocks and posterior surface of the thighs. The sensibility of the mucous membrane of the penis and rectum may also be dulled. If the lesion is sufficiently destructive, the muscular

power of the bladder and rectum may be seriously impaired, sexual power lost, and bedsores may develop.

Lesions of certain fibers of the cauda equina may produce a clinical picture very similar to that of conus disease. To be able to recognize and differentiate the two conditions is not only scientific, but extremely practical from the standpoint of treatment. While it is not probable that focal lesions of the conus will ever be amenable to surgical treatment, a limited number of cases of caudal disease have already been reported successfully treated by operation. Focal disease of either the cauda equina or conus medullaris may exist alone or in connection with disease elsewhere. Disease of both structures may coexist.

During the last three years it has been my fortune to observe nine cases in which disease of either the conus or the cauda was present, one of which came to autopsy. The lesions represented in these cases included focal myelitis, tumor of the conus and disturbances of function of these structures due to the following conditions: Injury to the vertebral column, tumor of the vertebra, and tubercular spondylitis. I have also observed one case of tabes dorsalis in which the symptoms of a conus lesion were present.

### THE WORK OF STARR AND KOCHER.

That the case may be studied more understandingly I wish before reporting them in detail to refer briefly to the work of Starr and others on spinal localization. Starr was one of the first to recognize the importance of the fact that focal lesions of the different spinal segments were accompanied by sensory disturbances confined to certain areas of the skin. After an extended study of the cases reported, and of his own, both antemortem and postmortem, he elaborated a chart relative to the lower extremities, to which the reader is now referred. According to Starr, disease of the third sacral segment is accompanied by anesthesia of the area marked S3; similarly, disease of other segments gives rise to anesthesia of areas designated by the corresponding segment number. Subsequently, Head constructed a chart based chiefly on his study of herpetic eruptions and areas of cutaneous tenderness present in visceral disease. The gaps in the cutaneous areas not affected by visceral disease, such as that from the second to the fourth lumbar segments, inclusive, were filled in by him from a study of cases, the result of disease or injury. The result of Kocher's work on spinal localization is shown in an accompanying chart representing the lower extremities only. Wichmann's chart for the lower extremities shows marked overlapping of many of the segments. His conclusions are based on a consideration of nerve distribution combined with clinical cases. The dissimilarity in the results obtained shows that either

cutaneous distribution is not constant, or that knowledge on the subject is imperfect. It is hoped that a study of the following cases may contribute something to the subject of spinal localization.

CASE 1.—Illustrating Myelitis or possible Spontaneous Hemorrhage, involving the Conus Medullaris:

J. M., male, aged 40, was admitted to the hospital, Oct. 4, 1898. When 17 years of age, had chancre, followed by secondary lesions. Several years ago used alcohol to excess. Claims that he drinks moderately of late. Two days previous to admission, while drunk, patient was exposed to cold and wet and slept all night in his wet clothing. The next day patient suffered with headache, nausea and weakness of legs. He was able to work all day. That night he slept well; next morning went to work as usual and continued until noon. About 1 p. m., after returning from dinner, the patient sat down and upon attempting to arise found that he could not, on account of weakness of his legs. He was brought to the hospital and after his arrival walked a short distance. The same evening patient noticed he was unable to retain his urine. No sensation was felt in the bladder or urethra, as it

Figure 1.

dribbled away from him. He was then able to control his bowels. Numbness of the skin about the gluteal and anal regions was noted by the patient. Superficial examination disclosed areas of partial anesthesia and analgesia on the posterior aspect of the buttocks and thighs. Sensation elsewhere normal. Patellar reflexes slightly exaggerated. Temperature normal. Bladder palpable two inches above pubes. Gait was very unsteady. No painful sensations experienced by the patient. For two days the bowels did not move. Magnesium sulphate was given and followed by involuntary bowel movements.

Examination on October 11, one week after admission, revealed the following condition: No symptoms referable to the cranial nerves, upper extremities or trunk. The lower extremities are somewhat weakened, especially both peroneal groups of muscles. Patient is able to support his weight on his toes. Extensors and flexors of the right foot slightly weaker than those of the left. Fibrillary twitchings are not observed; no atrophies; normal response to electricity. Patellar reflexes slightly exaggerated, more on the left. Achilles reflex absent, both sides. Both plantar reflexes present, but abdominal and cremaster absent. No incoördination. The gait is slightly spastic—paretic. Patient is able to walk better than when he

entered the hospital and says his legs feel stronger. Bladder is distended; the urine dribbles away and bowels move without producing any sensation. No pain has been experienced. Sexual power is lost. Sensory disturbances: Hyperesthesia of scrotum, penis and areas outlined in Fig. 1. In these areas the temperature sense is almost completely lost; a superficial pin-prick does not give the sensation of pain; a deep pin-prick is recognized. Slight anesthesia about the outer side of the left ankle. The process probably extends upwards as high as the lower portion of the first sacral segment. The testicles are tender on pressure. The anal sphincter is relaxed. The urethral mucous membrane is anesthetic to the passage of a sound. There is very little resistance offered by the membranous portion of the urethra.

The patient gradually improved in strength and on October

Figure 2.

21 the bowel movement was controlled. On November 2, it is recorded that the patient can retain urine and can feel it as it is voided. The patient was discharged Dec. 28, 1898. The area of hyperesthesia remained about the same in outline, although not as pronounced as on admission. The patient had gained full control of his bladder and rectum.

*Clinical Diagnosis:* Myelitis or possibly spontaneous hemorrhage, involving the conus medullaris; influence of lesion at onset extending as high as the fifth lumbar segment. The differential diagnosis between conus and caudal disease will be considered at the close of the article.

According to Sherrington, the skin of a given locality is supplied by a higher root than the muscles lying directly beneath that area, with the exception of the posterior surface of the thigh. Only the pilomotor fibers of the sympathetic ganglion and the sensory cutaneous areas of the corresponding spinal ganglion coincide in their distribution. According to Langley, the secretory fibers of the sympathetic ganglion correspond in a like manner. It may be noted that in this case the statement of Sherrington does not appear to agree with the

findings. Relative to the exact location of the lesion in the cord, it may be safely stated that in the early stage the lesion extended high enough to influence decidedly the fourth and fifth lumbar segments, and possibly slightly higher, since the patellar reflex was exaggerated. Subsequently, the effect of the lesion was confined to the sacral segments. The upper limit of the permanent lesion reached the level of the lower part of the first sacral segment. Whether it extended downward to the tip of the cord may not be stated. The lower limit of cord lesions is always difficult to ascertain, the chief aids being the reaction of degeneration, and the condition of the reflexes.

CASE 2.—Illustrating myelitis or hemorrhage in the conus and adjacent cord: L. S., female, aged 17, was admitted to the hospital, May 24, 1901. Three weeks before admission the patient began to have pain in the small of the back during the regular menstrual period. Did not sleep much that night. The next day felt as well as usual. Three days later she began to have pain in the back and knees. While on an errand, her

Figure 3.

knees suddenly gave way and she fell to the ground. She was unable to get up and was carried to her bed. Pain was felt in the legs, especially in the calf muscles. The pain was sharp, intense, cramp-like in character and continued for five or six days. Some tenderness of the posterior thigh muscles developed. Patient cried out when the legs were moved. Pain was increased on pressure. One week after onset of paralysis, incontinence of urine developed. Bowels were all right for one week after onset, when constipation began. Bowels were moved by cathartics. These soon failed, and the strongest became futile. Enemas also had little effect. Patient did not feel feces passing the sphincter. No fever, nausea or vomiting was present. Three weeks after onset a large bed sore suddenly developed. Family history negative. Patient had not recently been ill.

Examination May 26 shows no spinal deformity or tenderness. Bed sore in the sacral region the size of the hand. Bladder distended. Some weakness of quadriceps muscles. Legs may be drawn up and flexed on the thigh with considerable exertion. Plantar and dorsal flexion of the feet is impossible. The patient is unable to move the toes or evert either edge of

the foot. Peroneal group totally paralyzed. Outward and inward rotation of the hip is paretic. Unable to voluntarily force the thighs backwards. Levator and sphincter ani relaxed. Detrusor muscle paretic. Mucous membrane of the vagina and rectum slightly dulled to touch and pain sense. Muscle sense absent. Sensation disturbed in the areas outlined in figure 2. There is complete loss of sensation of pain, temperature and touch in the areas outlined about the buttocks and perineum. The same is true of the more deeply shaded areas about the feet and the outer side of the legs. The inner side of the legs was hypesthetic. The loss of the temperature and pain sense was more sharply outlined and extended slightly beyond the areas of cutaneous anesthesia. Areas that showed slight hypesthesia were analgesic to superficial pinprick, and temperature could not be distinguished.

It was necessary to catheterize the patient for several weeks.

Figure 4.

The pain in the legs had disappeared when the patient came to the hospital. After about two weeks, it reappeared, but not as severe as at the onset. It came in paroxysms, lasting about fifteen minutes, returning about every hour. This continued for about two weeks, and has not since returned. The bed sore has persisted, although it is growing smaller. The condition at last examination, Oct. 21, 1901, was very little changed, except that the bed sore was nearly healed, and the patient was gaining some control over the bladder and rectum.

Since pain in the legs was an important symptom at two different times during the early history of this case, it is not improbable that the cord lesion was accompanied by a slight meningeal affection. A myelitis is often associated with slight meningeal inflammation. Intra- and extra-medullary hemorrhage not infrequently take place at the same time. On the other hand, it is doubtful whether in such cases one is justified in assuming that a meningeal lesion coexists, since irritation of the sensory paths in the cord may be accompanied by

radiating pains and hyperesthesias. (Berndt, Vix, Kocher and Gowers.) In a given case the nature of the process and the severity of the pain would count for much in determining whether the meninges were involved.

CASE 3.—Illustrating Lesion of the Cauda Equina: C. S., male, aged 35, walked to the hospital and was admitted Oct. 22, 1899. The first symptom noted by the patient was pain in the right lower extremity and soon afterward in the left. The pains gradually became more severe, and the patient began to lose in weight. Before his admission to the hospital he had been treated for sciatica. Upon admission to the hospital pain in the thighs and legs was very severe, but not increased on pressure. Power of the lower extremities somewhat impaired. A tumor having its apparent origin in the lower

that the distribution of the anesthesia, and the bladder and rectum disturbances indicate that the fibers coming from the third, fourth and fifth sacral segments, or, in other words, the fibers coming from the conus, were much more seriously affected by the compression than the remaining fibers of the cauda equina. The fibers from the conus hang in the center of the whole bundle of fibers constituting the cauda equina, and there is no apparent reason why they should suffer greater injury from compression than those immediately surrounding them. Thorburn, however, has previously made similar observations relative to compression of the cauda equina. In his book on surgery of the spinal cord, he writes:

Figure 5.

lumbar spine was readily palpable through the abdominal walls. An area of hypesthesia corresponding to shaded portion of figure 3 was detected. During the following two months the hypesthetic areas became anesthetic, analgesic and thermesthetic. The patient lost control of his bladder and bowels. The anal sphincter became relaxed. The mucous membrane of the penis became anesthetic to the passage of a sound. Notwithstanding these symptoms, the patient could move his legs with considerable freedom. Their movement was restricted apparently by the increased pain produced. The electrical reactions were unchanged. At first the patellar reflex was slightly exaggerated.

At the time the patient was discharged, the reflexes were about normal. The tumor had increased rapidly in size and apparently involved the bodies of the vertebrae in the middle and lower thirds of the lumbar spine. It was probably a sarcoma. Unfortunately, the patient moved from the city, and I am not able to give the subsequent history of the case.

From the location of the tumor the lesion was probably compression of the cauda equina in the lower lumbar region. It will be noted, however,

Figure 6.

"In a pressure lesion of the entire cauda equina the central fibers are more seriously injured than those surrounding them."

CASE 4.—Illustrating traumatic Myelitis of the Conus and adjacent Cord: J. S., male, aged 40, was admitted to the hospital May 21, 1900. Patient fell a distance of ten feet, striking on his shoulders, doubling his spine. He immediately felt numbness in the right lower extremity, and pain in the small of the back. He could move his legs, but could not get up on account of pain in his back. No pain was felt in his lower extremities. No pricking nor tingling sensations were experienced. Before arriving at the hospital the patient noted that the penis and scrotum were anesthetic.

Examination, May 25: Slight angular deformity present at the first lumbar vertebra. Two small blebs on either side of the gluteal fold, about four inches above the anus. Excoriation about the head of the penis. Both lower extremities are weak, but all their movements, including flexion, extension and rotation, can be executed. No atrophies. Reflexes—patellar, Achilles, plantar, cremasteric and abdominal absent. Reflexes of upper extremities normal. Retention of urine exists, and

when the bladder is overfilled the patient experiences dull pain. The passing of a catheter is not felt. The anal sphincter offers slight resistance. The patient is not conscious of the examining finger, except in the region of the prostate. Rectal tube is not felt until the sigmoid flexure is nearly reached. No pain along the course of the nerves. Muscular sense everywhere intact. Sexual power lost. Sensation is disturbed in the areas outlined in figure 4. The areas shaded heavily corresponding to the cutaneous distribution of the second, third fourth and fifth sacral segments were anesthetic to touch and to ordinary pin-prick. A deep thrust of the pin produced the sensation of pressure and slight pain. Temperature sense lost. The areas shaded lightly were uniformly anesthetic to the camel's hair brush. It will be noted that the cutaneous area supplied by the first, second, third, fourth and fifth sacral segments are affected on both sides equally. In addition, on

Figure 7.

the right side the cutaneous distribution of the twelfth dorsal, first, second and third lumbar segments are involved. Electrical reaction normal.

**Diagnosis:** Traumatic myelitis involving the conus medullaris, influence of lesion extending as high as the twelfth dorsal segment. **Etiology:** Dislocation or fracture of the first lumbar vertebra. **Subsequent course:** Patient was seen last Oct. 21, 1901. He was able to walk and do some work. Areas of anesthesia confined to the distribution of the sacral segments. He had regained control of the bladder and rectum.

Since the fibers of origin of the cauda equina completely surround the conus medullaris, one might expect more serious symptoms referable to the cauda in a traumatic lesion of the conus, such as we assume exists in this case. Relative to this point, however, Oppenheim, Schultz, and Sarbo have each reported a case, with autopsy, in which the conus was destroyed by trauma, and the fibers of the cauda remained intact. When one compares the relatively delicate structure of the conus with the coarse fibers of the cauda that surround it, it

is easy to understand how a sudden and temporary displacement of the bodies of the vertebræ from fracture or dislocation might seriously injure the conus and produce few or no symptoms referable to the cauda equina. That simple compression of both of these structures may result in disturbing the function of the conus without affecting the fibers of the cauda equina is well illustrated by the following case of tubercular spondylitis:

**CASE 5.**—Illustrating uniform Compression of the Conus from Spondylitis: J. O'M. came to Dr. Preble's clinic, complaining of pain in his back. Examination showed slight deformity and tenderness in the region of the first lumbar vertebra. There was little or no loss of power in his legs. There was a sharply defined area of hypesthesia corresponding to the shaded outline in figure 5. It will be noted that there was dulled sensibility in the cutaneous area supplied by the whole sacral cord. The function of the bladder and rectum was undisturbed. The sexual power was intact. No painful sensations were experienced, with the exception of tenderness at the

Figure 8.

seat of the spondylitis. The patient gradually improved, so that he is now able to work. The deformity in the lumbar region has nearly disappeared. No trace of the cutaneous anesthesia is to be found. It is fair to presume that the hypesthesia was due to compression of the conus by the inflammatory exudate of the spondylitis, and that as the exudate was absorbed, the conus hypesthesia disappeared.

**CASE 6.**—Illustrating traumatic Myelitis or possibly Hemorrhage involving the Conus and adjacent Cord: R. received an injury to his dorso-lumbar spine, resulting in sudden paralysis of the legs, bladder and rectum three years ago. The patient is now able to work and has regained control of his bladder and rectum. Fig. 6 represents the sensory disturbances still present as the result of the injury. The lighter shades are intended to indicate hypesthesia, the darker shades anesthesia to a camel's hair brush. Pain sense was dulled and temperature sense lost in the area of darker shade. It will be noted that the sensory disturbances indicate that the lesion which now remains is symmetrical, and involves the cord as high as the twelfth dorsal segment. The function of the whole sacral cord, as shown by the cutaneous anesthesia, is more

*Autopsy* showed miliary tuberculosis the immediate cause of death. A tubercular tumor was found occupying the upper sacral and lower lumbar cords. The upper limit of the lesion was at the lower part of the second lumbar segment, higher on the right than on the left side.

tion of a given root, it was necessary to divide five roots above and five below the one investigated. Head claims that the areas of distribution mapped out by him on the basis of herpetic eruptions and tenderness in visceral disease do not overlap and that they correspond fairly closely to the areas of Sherrington, determined by a study of posterior root distribution. He also claims that the great difference between the root and the cord supply is that the root supply overlaps greatly, while the cord supply does not. Finally, Head concludes that the mechanism for touch sensation in the spinal cord overlaps, and that the mechanism for pain and temperature and trophic influences does not overlap, or at least not to the same extent as the overlapping of the touch sensation. His conclusions receive support from a study of this series of cases. It was also noted that the pain and temperature areas approximately coincide. Refer-

Chart after Wichmann.

In all the cases of this series the disturbance in temperature and pain sense was more sharply defined and, as a rule, extended slightly beyond the areas of cutaneous anesthesia. Areas in which tactile sensibility was only slightly dulled often showed analgesia and thermesthesia. Such observations have been previously made by Starr, Thorburn and others who have given attention to these particulars.

Sherrington's experiments on the posterior spinal roots show a marked overlapping of the cutaneous distribution. Cutting one root was accompanied by no loss in the sensation of touch. Such great overlapping was present that in order to map out the area of distribu-

Rocher's chart.

ring again to the charts of Starr, Head, Koehler and Wichmann, it will be observed that Wichmann's chart shows greater overlapping of areas than any of the others. This would naturally result from the basis upon which the outlines were constructed. The distribution of peripheral nerves was consulted largely and it is known that they overlap to a marked degree. Although these charts differ considerable in detail, they resemble each other coarsely and for clinical purposes any one of them would certainly be approximately correct. Viewed from the standpoint of accurate physiology, they probably do not represent final knowledge on the subject. Indeed, it will not be possible to draw hard and fast lines descriptive of cutaneous areas of spinal segment distribution until a great many cases have been studied in connection with autopsies. I be-

lieve a study of this series of cases contributes certain points relative to the physiology of the sensory distribution of the lower cord.

It will be observed that there is great similarity in the outline of the shading representing the areas of anesthesia about the posterior thighs, buttocks, perineum, penis and scrotum. These areas are fairly symmetrical, and correspond very closely to the areas said by Starr and Kocher to represent the distribution of the third, fourth and fifth sacral segments. Figures 3 and 9 show pure types of conus anesthesia. The area mapped out resembles somewhat the patch on saddle-breeches. Since this peculiar area is repeated in every one of the nine cases and in many others in the literature, it is fair to presume that lesion of a certain portion of the cord or cauda equina is regularly accompanied by such an area of anesthesia. From a study of these cases and those reported, especially the cases collected by Starr and Kocher, I believe the areas outlined in Figures 3 and 9 are due to disease of the third, fourth and fifth sacral

plies it lies directly above that for the saddle-breeches area. According to Head, lesions of the fifth and fourth lumbar segments produce sensory disturbances on the outer and inner sides of the leg respectively. Cases 2 and 7 are completely in accord with such a distribution. It may be noted that the outlines in the nine cases here reported corroborate very closely the work of Starr about the buttocks, perineum, penis, scrotum and posterior thighs, and that of Head about the feet and legs. It is also worthy of note that in connection with the saddle-breeches area the anesthesia of the posterior thighs did not extend downward as far as the bend of the knee, except in Cases 4 and 8. In Case 8 it is probable that disease of the second and third lumbar segments caused the anesthesia of the legs to become continuous with the anesthesia of the thighs. In Case 4, injury to the second and third lumbar segments caused an extension of the anesthesia downwards beyond the bend of the knee. This series of cases confirms splendidly the work of Starr relative to the posterior thighs, and does not at all con-

Chart after Head.

Author's chart.

segments, or to disturbance in function of caudal fibers leading to those segments. In case the lesion extends higher in the cord, involving the second sacral segment, this same area is extended so as to conform very closely to that outlined by Starr under the first, third, fourth and fifth sacral segments. (Figures 1, 2, 5, 7, 8 and the deeper shades on the buttocks of 4 and 6.) Thus far the outlines in this series agree perfectly with Starr's chart.

I wish now to call attention to the peculiar slipper-shaped area of anesthesia about the feet in figures 4, 5 and 6. By referring to the charts, it will be seen that Head has outlined such an area. Figure 1 shows an area of anesthesia about the left outer ankle, suggesting the beginning of the slipper-shaped area. Head has shown reasons for believing this area to be supplied by the first sacral segment. These cases furnish good evidence in support of the existence of such an area and it seems very probable that the cord segment which sup-

plies it lies directly above that for the saddle-breeches area. Head extends a strip downward from the buttocks to some distance below the knee. Kocher and Wichmann extend a continuous strip from the buttocks down the posterior thigh and leg to the feet. These cases show such uniformity in outline that one is compelled to alter somewhat the charts previously constructed relative to the lower extremities. I feel justified in offering a new provisional chart based upon a study of this series of cases in connection with those previously reported. It is to be understood that as new cases are recorded, no doubt still further alterations in the areas outlined will be made.

#### DIFFERENTIAL DIAGNOSIS BETWEEN LESIONS OF CAUDA EQUINA AND CONUS MEDULLARIS.

When disease of the cauda equina is accompanied by typical symptoms, there may be no difficulty in recognizing it. Except when due to trauma, disease of the

cauda usually develops slowly, producing symptoms more or less characteristic of root disease. The patient first experiences pain upon movement of the lower extremities; later the pain becomes spontaneous and persistent, with exacerbations. Subsequently, anesthesia begins and when the lesion is a uniform compression of the cauda, it has been observed in a few cases that the function of the central fibers was the first disturbed. Bladder and rectum symptoms may appear early and are usually present before anesthesia becomes pronounced. Muscular weakness is present in proportion to the pressure on the motor fibers and, as a rule, does not appear until pain has become a prominent feature. The paralysis is characterized by loss of muscular tone. An early examination may show exaggerated reflexes. Later they are diminished and finally lost. Atrophies develop. The electrical reactions may be altered. Decubitus has been noted. In reference to the height of the caudal lesion, if no local signs relative to the spine are present, to aid in locating the lesion, it is fair to presume that the upper limit of the lesion is just above the exit of the highest nerve that is disturbed in its function.

Disease of the conus is characterized by the sensory and motor symptoms described in the beginning of this article. In addition, the symptoms are likely to develop rapidly. Sensation may not be disturbed alike for all qualities. The pain and temperature sense is likely to be more seriously affected than the touch sense. Provided the conus lesion does not exert an influence on the caudal fibers, severe pain is absent. Decubitus is more likely to occur than in caudal disease. Above all, that which characterizes disease of the cauda equina is pain. A conus lesion may be associated with pain, provided the cauda or meninges are also involved. That which speaks directly for a conus lesion in a given case is the absence of pain. Differential diagnosis of the two conditions is important, as disease of the cauda equina may often be amenable to surgical treatment.

I am very greatly indebted to members of the Attending Staff of Cook County Hospital, who have so kindly placed their cases at my disposal.

**Singular Fatality.**—A little girl, aged 12, met with a singular death at Brighton, England, recently. In biting an apple she broke a tooth, a splinter from which penetrated near the throat, setting up such profuse hemorrhage that the child succumbed.—*Brit. Jour. Dent. Sci.*

## PLASTIC SURGERY. WITH CASES.—FORMATION OF NEW CHEEK.

C. E. RUTH, M.D.

Professor of Anatomy and Clinical Surgery, Keokuk College of Physicians and Surgeons.

KEOKUK, IOWA.

Plastic surgery principally concerns the repair of skin or mucous membrane defects. Direct approximation of edges, by undermining and stretching, fixed by sutures, is easy and sure of satisfactory results if tension is not too great and the tissue healthy. This method may be aided by lateral subsidiary incisions to facilitate sliding, the lateral clefts being left to granulate and cicatrize, or are closed by grafts placed at once, or as soon as good healthy granulation tissue has formed.

Flap formation, with or without twisting of the pedicle, will in some cases serve a useful purpose. Marginal connection of flaps from a distant part of the body, re-

Figure 1.

leased from pedicle connection later, has a very limited field. The confinement is most irksome; besides, the vitality of the disconnected flap is feeble for a long time. In all cases where the new skin can be made to rest upon an underlying, healthy fresh wound, free from blood, or upon a granulating surface throughout, the chances of success are certainly good—especially if even a very moderate blood supply can be obtained for the flap. Where no base exists upon which to rest the flap, where subcutaneous connective tissue, skin and mucous membrane are lost, as in cases of cancerum oris, or the much more common deformity of almost total loss of one side of the face resulting from the use of cancer paste to remove carcinoma, real or imagined, the difficulties are increased a hundredfold.

**CASE 1.**—Such a case was presented at my clinic in September, 1900, in the person of Mr. R., of McCausland, Iowa, referred by Dr. F. C. Smith. He gave a

history of carcinoma of the lip and cheek twice operated upon; it quickly returned, but was subsequently treated by a so-called cancer specialist, and presented the appearance partly indicated in the photograph which I herewith present as Fig. 1. More than the right half of the upper lip, all of the cheek from the nose to one-third inch from the right eye, to three-fourths inch from the ear, and to the lower portion of the jaw were gone, together with part of the malar bone, and all of the external portion of the right superior maxillary with most of its alveolar process, leaving the entire right side of the mouth and tongue exposed, as well as a considerable opening into the nasal cavity and a recess two inches deep extending back to the posterior internal wall of the maxillary sinus. Saliva constantly discharged from the lowest part of the opening. Strange to say, this enormous gap had cicatrized, all bone was covered, and the surface had every appearance of being healthy. I was informed that it had been in this condition for one year.

Figure 2.

To close this enormous defect I raised a flap, as indicated in the above cut. No. 1, by the heavy ink lines, and sutured it in position. A small flap from farther down the neck was used to close the front of the defect made by removing the large flap. The other borders were undermined and the flap space narrowed sufficiently that twelve grafts entirely closed the large wound in ten days so as to leave almost no deformity on the neck. I was compelled to disregard the source of blood supply much more than I liked, but raised considerable subcutaneous tissue to increase the number of vessels to the flap. A small portion of the flap sloughed by the side of the nose, and the suture bite was lost under the eye. The portion of the flap which failed to secure connection rapidly contracted and became inverted, and in a few weeks had formed an almost complete epithelial lining on the inner side of the remaining portion of the flap. The amount gained by the first operation is shown

by the heavy ink line on Fig. 2, all being closed practically from below to this line.

The next step consisted in cutting loose the remaining left half of the upper lip from the nose, undermining its attachments far out upon the cheek, and drawing it so far to the right as possible, where it was anchored. The lower lip was then loosened extensively by undermining far down over the chin. It was not possible to unite the old cheek flap to the upper lip as I had hoped. To meet this difficulty, I divided the lower lip vertically and extended the right side upward between the old flap and the end of the upper lip, and with it nicely filled in the space between them and sutured all in position. At the point where I divided the lower lip vertically I was compelled to make the temporary right angle of the mouth, stitching the lip securely in place; the result was all that could be expected, as union was obtained throughout. The mouth was, however, drawn far to the left side by muscular action and was very small. Fig. 3

Figure 3.

shows by the ink line the defect at the side of the nose yet to be closed.

Three weeks later the course of the right temporal artery was carefully outlined and a flap raised with the artery running directly through its center. The flap was made large enough to close the remaining space, with one-half to three-fourths of an inch to spare, at all points on the margin. The margins of the gap were then freshened by splitting the integument, and a continuous cut made one-eighth to one-fourth in from the margin and the inner side inverted so that it could be sutured on the inside of the flap margin. The edge of the flap proper was carefully sutured to the skin surface or edge with which it was to be continuous. The bearing contact surface of the flap margin was thus increased at least twice or three times what it ordinarily would have been. The pedicle of the flap was left attached at its base; one week later the integument was

removed from beneath the pedicle and the latter was sutured in position, while a portion of the tissue removed from beneath the pedicle was used to form a new lower

head along the course and on each side of the anterior branch of the temporal artery. The right angle of the mouth was now extended to the margin of the new temporal flap. Fig. 4, taken one week after the last grafting was done, gives a better explanation than words.

Fig. 4.—Appearance two weeks after last operation.

Figure 6.

Fig. 5.—Appearance five months after last operation. eyelid. Twenty-eight grafts were used to close the defect left by the removal of the flap from the temple and fore-

Fig. 7.—After removal of one-half of tongue, two inches of lower jaw and submaxillary glands, etc.

CASE 2.—Mr. Albert R. was referred to me by the party who used the caustic. A history was furnished of a growth which was supposed to have started from the

right tonsil and was three times operated upon, and lastly was eaten off by my erstwhile friend of the guarantee-cure fame of Dubuque. The result is tolerably well shown in Fig. 6.

The body of the right superior maxilla was almost entirely gone with all of the soft parts over it, part of the upper lip and the lower lip to the lower margin of the inferior maxilla. The inferior maxilla was gone at one point, and surmounting the point of solution of continuity in the inferior maxilla, and involving the right side of the tongue was an epitheliomatous mass more interesting than agreeable to contemplate. With the head very low an incision was made wide of apparent deposit around the outer side of the growth, and an incision was extended from this point downward to the cornua of the thyroid cartilage on the right side. The integument was separated on each side. A needle was then thrust through the center of the tongue, immediately above the hyoid bone, armed with a silk loop; the needle was then carried out on the right side in front of the external

attachments far out upon the left cheek, the lower lip and soft parts over the chin were likewise undermined, so as to glide as nearly as possible into the normal positions for such structures, and to reach to the flap to be raised for closing the main defect. The cicatricial tissue which extended to the lower part of the jaw below the angle of the mouth was detached along the tegumentary margin and turned upward, remaining attached to the upper border of what was left of the jaw in front, and was sutured in place as a reinforcement to the new flaps and as an epithelial graft on the inner side of the new cheek. The main flap to fill in the remaining defect was obtained principally from in front of the ear with the pedicle extending down on to the neck. The marginal union was effected as in the former case, by turning in the skin edge all along the margin to act as epithelial grafts on the margin for the inner surface of

Figure 8.

carotid above the facial and lingual arteries, and a strong iron tinned wire was carried through by the silk loop so as to bring, when tightened, the entire blood supply to the right half of the tongue perfectly under control. The right side of the tongue was now removed with little difficulty and slight loss of blood. About a two-inch piece was removed from the inferior maxilla, together with the submaxillary gland and submaxillary lymph glands. Microscopic examination showed the growth to be an epithelioma, and that nearly all of the tissue removed was involved by malignant infiltration. The large surface left to granulate was carefully watched, and any suspicious points were cauterized with the thermocautery after testing with the arsenic-alcohol solution. This plan was followed until cicatrization was practically complete in about six weeks. Figs. 7 and 8 show condition at this time.

Under chloroform anesthesia the remaining part of the upper lip was severed from the nose and other bony

Fig. 9.—Two weeks after operation.

the new cheek, as well as to protect the raw contact surface. Union was prompt, complete and perfect, except a very small sinus at the ala nasi. The defect in front of the ear left by removing the flap was narrowed as much as possible at the time of operation, and a week later was grafted from the arm, about twelve grafts being required. Fig. 9 illustrates the condition two weeks after forming the new cheek, and one week after the grafting was done for closing the defect left by the removal of the flap from the cheek. For six days and nights heat was applied to the cheek as near 125 Fahrenheit as possible. I take pleasure in presenting this case now, two and a half months after operation. I prefer to leave the pedicle connected at its base of original attachment as furnishing a much safer blood supply to meet the results of accident and cold than would be possible where marginal nutriment alone was depended upon.

In making skin or mucous membrane grafts to close

defects of skin or mucous membrane, care must be taken to include only the skin or mucous membrane proper without any fat; and usually a piece is transplanted three-sixteenths inch by one-fourth inch and always transferred at once to its final resting-place on a fresh, raw or healthy granulating surface, and after being secured in position is not disturbed for at least three days. Perfect draining opportunities must, however, be provided, and strict aseptic precautions must be maintained throughout. If only the epithelial layer is used as a graft the resulting cicatrix is feeble, and from slight irritation the surface recently closed is likely to lose all the protection the physician was able to procure in weeks of patient toil.

CASE 3.—In March of this year a little girl 7 years of age was referred to me by Dr. Tobin of Mt. Sterling, Iowa, for cicatricial contraction and flexion, to an extreme degree, of the ring and little fingers of the right hand from a burn produced eight months before by a rope being drawn rapidly through the hand. Previous experience had convinced me of the folly of attempting to cure the case while the mass of cicatrix remained. I carefully removed all the scar tissue, at points exposing the flexor sublimus and profundus tendons, until the fingers could be easily and perfectly straightened, except a slight defect at the last joint of the little finger. The entire palmar surface of each finger was denuded. Two pieces of skin were next carefully removed from the forearm of the same limb of sufficient size to nicely cover the defects after allowance was made for shrinkage. The pieces removed were one-third by two and one-half inches. These large pieces or grafts were carefully sutured in place with fine silkworm gut tailings, as I could not trust a child of her age to leave the dressings entirely undisturbed. The hand was kept wrapped in an abundance of cotton and resting for six days and nights on a hot-water bottle at 125 Fahrenheit. Union was complete throughout on the little finger. Slight slough took place in the center of the ring finger flap, but not enough to be serious. The fingers were kept extended by splint for three weeks. The tendency to contraction was very slight indeed when last reported. This is the first case in which I have attempted to transplant bodily so large a piece of skin, and the first in which I know of sutures being used to retain a graft.

The plastic face cases are by far the heaviest and most extensive I have undertaken, and the worst I know to have been closed by any form of plastic procedure.

## A NEW DRY SURGICAL DRESSING.

ALBERT C. BARNES, A.M., M.D.

Late of Pharmacological Institute, University of Heidelberg; Member of American Therapeutic Society.

AND

HERMANN HILLE, PH.D.

Late of Chemical Institute, Heidelberg; Formerly Assistant, Physiological Institute, Würzburg.

PHILADELPHIA.

Whatever interest the manifold substitutes for iodoform may have for the surgeon or dermatologist, they are too similar in chemical construction and attributes to claim the serious attention of the scientific pharmacologist familiar with the laws of the relationship between chemical constitution and physiologic activity; the latter knows that clinically they must be of practically identical worth and have all the same limitations, disadvantages or dangers. Surgeons employ the odoriferous, toxic, non-antiseptic iodoform in the treatment of infected wounds because they know that not one of the

substitutes is of equal value in cleaning the wound of the products of septic and necrotic processes and in stimulating healthy granulation. Aside from the stigmatizing odor of iodoform, the need of a substitute therefor has received additional emphasis by the fact that within comparatively recent times surgeons everywhere have frequently recorded more or less severe forms of headache, with or without anuria or albuminuria, which were clearly ascribable to the local use of but moderate quantities of iodoform.

Practically all of the iodoform substitutes thus far proposed belong to one or the other of two classes and have, therefore, certain advantages and disadvantages. The first group comprises those which, like iodoform, depend for their activity upon the presence of iodine loosely combined chemically so that free iodine is eliminated by contact with the wound secretions. The best known of these is aristol (dithymol diiodid), which is of certain value in a limited number of cases but which is too easily decomposed and too expensive to employ even if it fulfilled the requirements of a satisfactory dressing. Clinically the antiseptic and granulation-stimulating properties of free iodine are desirable, but there are other striking indications for treatment in infected wound surfaces which are not met by these iodine-bearing powders.

To the second group of iodoform substitutes belong the large number of bismuth compounds, depending for their activity upon bismuth which, as is well known, acts as a protective and diminishes secretions. Kocher of Bern employed and recommended bismuth subnitrate as a dressing for wounds attended with pus formation and excessive secretions. Hans Meyer of Marburg showed that the drying effect of bismuth is due to the mechanical plugging of the blood and lymph capillaries by minute particles of bismuth and that, anatomically considered, the effect is analogous to the healing which takes place under a scar. The newer organic bismuth compounds are of value clinically because they diminish wound secretions in the manner above indicated, but are possessed of but feeble, if any, antiseptic power and have no stimulating effect upon granulation; this is true not only of dermatol (subgallate) but also of the host of other bismuth compounds that have been offered under fanciful names.

By application of the newest procedures of synthetic chemistry, the writers have endeavored to produce a substitute for iodoform that would chemically, pharmacologically and clinically, possess the attributes which the teachings of modern surgery assert are necessary to meet the indications for treatment in infected wounds. Such a powder should be antiseptic, astringent, sedative, desiccating, stimulating to granulation and non-toxic. From a chemical standpoint the first step is to combine, synthetically, bodies which will gradually dissociate when brought in contact with wound secretions and thereby unfold their chemical and physiologic effects. We produced a series of compounds, all entirely new definite chemicals, and studied their chemical, pharmacologic and clinical properties. The essential features of one of these compounds, monoiodid-di-bismuth-methylene-dicresotinate produced for the first time by ourselves, are herewith briefly presented. This body is synthesized from cresotinic acid, formaldehyde, bismuth hydroxid and iodine in the following manner: Cresotinic acid, the least toxic and strongest antiseptic of the phenol group, is treated with formaldehyde and the thereby resulting methylene-dicresotinic acid is chemically com-

bined with iodine and bismuth hydroxid. This yields monoiodid-di-bismuth-methylene-di-cresotinate which has the structural formula

This body is a pink, impalpable, odorless, tasteless and insoluble powder containing 45 per cent. of bismuth, 15 per cent. of iodine and 3 per cent. of formaldehyde. It is a well-known chemical law that when iodine and formaldehyde are combined, as they are in this body, they are dissociated *in statu nascendi* from their combination under the chemical and physical conditions present on wound surfaces. This evolution of free iodine and free formaldehyde takes place *gradually*, as can be easily demonstrated. The effects of this powder on a wound are those of bismuth, iodine, formaldehyde and cresotinic acid, i. e., antiseptic, astringent and alterative. The clinical use of the powder was preceded by bacteriologic tests and experiments on animals. Administered to dogs in doses of two grammes (30 grains) three times daily, it produced no toxic symptoms; the only effect noted was the production of constipation. The organisms of pus, as well as cultures of colon and typhoid bacilli, kept at 40 C. for from three hours to two days in contact with the powder, show no growth upon transplantation to fresh culture media; this fact illustrates the long-continued antiseptic power due to the gradual splitting off of the constituents.

For six months past the powder has been in constant daily use in several hospitals as a dressing after operations and in the general class of out-patient surgical cases in which are present active inflammatory processes accompanied by disorganization of tissue and excessive discharges. In the post-operative cases, union by adhesion or first intention was obtained in every case. Its use in infected wounds (burns, scalds, abscesses, suppurating surfaces, leg ulcers, etc.) showed remarkable effects in checking pus formation, drying secretions and in promoting granulations. In the out-patient surgical department of the Pennsylvania Hospital where the powder has been tried side by side with iodoform, aristol and several other dusting powders, it was noted that it uniformly cleans a wound better than any of the others, has an equal if not greater influence on granulation and induces more rapid healing. In no case have toxic effects of any kind resulted nor has it been necessary to discontinue its use because of disagreeable symptoms. This powder is interesting from a purely scientific standpoint because it is a new synthetic compound; clinically it is interesting because it is a compound of bismuth, iodine and formaldehyde so combined chemically that its active constituents are slowly split off, so that their effects are long drawn out and are not irritating or toxic. A detailed clinical report of the cases treated with the powder will be published later.

**Ice or Heat for Local Application.**—*Memorabilien* quotes Ewart to the effect that he has frequently found ice effective in painful articular rheumatism, arthritis and other affections which were aggravated or at least not improved by the application of heat. He rubbed the aching part with a smooth piece of ice and found that this gentle massage and cold cured a number of cases of acutely painful rheumatic arthritis of the hip-joint which had resisted all medicinal treatment and even baths of hot air. He also found that it relieved at once the severe pleuritic pains at the base of the lung in a number of cases of acute pneumonia.

## NEW METHOD OF ANCHORING THE KIDNEY— A PRELIMINARY REPORT.

BYRON B. DAVIS, M.D.

Surgeon to Immanuel Hospital, Professor of Principles of Surgery and Clinical Surgery, Omaha Medical College, etc.

OMAHA, NEB.

If a multiplicity of methods is an indication of unsatisfactory results, nephropexy must be the least satisfactory operation known to the surgeon. Dozens of methods have been exploited, each with a claim of superiority, but all based on four cardinal principles.

1. In April, 1881, Hahn reported his first cases of nephrorraphy for movable kidney. The sutures were passed through the fibrous capsule proper, the kidney being fastened to the edges of the deeper structures of the lumbar wound. Many slight modifications of this method have been made, but the principle of all has been the same as that originally used by Professor Hahn.

2. The method of decortication. Tuffier was the first to practice this method. He dissects off a portion of the posterior surface and convex border of the proper capsule of the kidney, and the organ is held into the wound by sutures, thus obtaining direct union between the deep muscles and fascia and the parenchyma. Jacobson modified this operation by dissecting off a flap of the fibrous capsule and stitching it to the lumbar fascia and muscles. Others make a double flap of proper capsule and suture each flap to the respective wound edges.

3. Senn's ingenious method, by which the kidney is held in position by a sling of gauze about the upper and lower poles, and the whole wound allowed to heal by granulations, is now one of the recognized principles of treatment of this troublesome disease.

4. Vulliet's method of making use of a strip from the tendon of the erector spinæ muscle to underrun the fibrous capsule, the free end of the strip of tendon being then attached to the muscle, illustrates a fourth principle in the treatment.

### DISAPPOINTMENT FROM ALL METHODS.

Surgeons have been much disappointed in the results of all these methods. Relapses are frequent and the more carefully one follows up the after history of his cases, the less confidence he is likely to have in his results. I know of some of my cases that have relapsed and have been impressed with the number of cases that have come to me with freely movable kidneys and bearing the scar of a previous operation done by well-known skilful surgeons. The adhesions between the true capsule and the lumbar structures are not likely to be firm. They become stretched in time and the kidney is likely to become as movable as before. The same may be said of the Senn method. No matter how firmly the kidney is held in place by the cicatricial tissue at first, we all know the later history of cicatricial tissue and there is no reason to suppose that in this region it will behave in any different manner than usual. All know the fate of large numbers who were subjected to the McBurney operation for hernia a few years ago, the plug of cicatricial tissue acting well for a time, but finally softening and stretching, allowing relapse of the hernia. Another theoretical objection to the Senn method is the effect of so much scar tissue upon so delicate an organ as the kidney.

Flaps of the true capsule stitched into the wound have appealed to me as being the best of the tried methods. But even here we have to trust to the adhesion between capsule and wound structures remaining intact without

stretching. Results show that even after this operation there are frequent relapses.

#### NEW METHOD BY MUSCULAR ATTACHMENT.

The use of a tendon of the erector spina appeals to me as better than the others described, except that it is difficult of execution and there is a question whether the free end will remain firmly fixed to the muscles. The method I wish to propose can best be explained by a report of the only operation yet done by this technique.

A. J., an unmarried female, aged 21, has frequent gastric crises and constant lumbar pain, especially on the right side. She lost 25 pounds in weight during the past year and is very anxious for relief. On examination, the right kidney is found freely movable, falling so low that the upper pole can be felt on bimanual examination. The left kidney is also somewhat movable. She entered Immanuel Hospital Nov. 9, 1901, and an operation was performed on the right side November 11.

Quadratus lumborum.

The incision extended from the lower rib to near the crest of the ilium, a hand's breadth to the right of the spinous processes of the vertebrae. The fatty capsule was reached just anterior to the outer border of the quadratus lumborum and was opened and a large part of it trimmed away. The kidney was pushed into place by a cylindrical pad placed under the abdomen.

#### DETAILS OF THE PROCEDURE.

When the kidney was well exposed, an incision was made through the proper capsule from two cm. below the upper pole to a point two cm. above the lower pole. This incision was placed vertically on the posterior surface near the convex border. The capsule was stripped loose from the kidney substance for a distance of three-fourths of an inch anteriorly and posteriorly to the incision in the capsule. From the upper and lower extremities of the vertical incision a perpendicular incision three-fourths of an inch long was made through the

capsule, this giving two flaps of capsule three-fourths of an inch wide by about two and one-half inches long.

Next a strip—the thickness of a little finger—of the other border of the quadratus lumborum muscle was split from the remainder of the muscle, the fibers being separated by the handle of the scalpel. This separation extended from the muscular attachment to the twelfth rib downward for two and one-half inches, or the slip in the muscle was made as long as the length of the capsular flaps before described.

An artery forceps was passed through the slit in the muscle, made to grasp the free border of the posterior flap of the kidney capsule and then withdrawn, bringing the flap of the kidney capsule through the slit in the muscle. The two capsular flaps were next brought together over the bundle of muscular fibers thus isolated from the border of the quadratus lumborum, and stitched

a. Erector spinae. b. Quadratus lumborum.

together with a running suture of fine chromicized catgut, the needle being allowed to penetrate the muscular bundle at two or three places. The lumbar wound was next closed by tier sutures of catgut, the skin wound being closed with horse-hair. Aside from a slight infection, the wound did well.

The patient never had a temperature above 99  $\frac{2}{5}$  degrees, was up on the twenty-second day and the kidney thus far is in place and the patient freed of her former symptoms. It is, of course, too early to predict the final results.

This method is reported because it seems to me to represent a new principle in treatment. We have here a portion of muscle which can not become loosened from the kidney, and which continues its own physiological function. I can see no way of the kidney thus anchored becoming loosened.

It has occurred to me that possibly the contraction of the muscle may give rise to pain or inconvenience. Inasmuch as by all the older methods, the effort has been made to effect as close an organic union as possible between the kidney and the deep lumbar muscles and fascia, and the more close the union the better the results were considered, I can see no objection to the method here proposed.

After writing the above, I found in the *New York Medical Journal* of Dec. 7, 1901, a short article by Carl Beck, New York, "On a New Principle in Nephropexy," which I take the liberty of quoting: "The principle of this—as it seems to me—new procedure consists in suspending the kidney after having buttonholed it, on the fibers of the nearest muscle. I may be permitted to give the following preliminary report: In a woman of 24, the right movable kidney, after being exposed by a lumbar incision, was perforated near its lower pole by a trocar of moderately large size, a procedure which caused but little hemorrhage. The margin of the spinalis dorsi muscle was incised then and a bunch of fibers, just large enough to pass the renal buttonhole, mobilized. By a Pean forceps, this band-like muscular flap was drawn through the renal hole made by the trocar. Then the end of the flap was fastened somewhat below its former muscular bed by iodoform-silk sutures. Thus the kidney was held *in situ* only by living tissue. There was no reaction and the operation seems to be a success."

The principle of this method is the same as my own, an effort to hold the kidney in its fixed position by living muscular tissue. But in my method there is, first, not so much traumatism to the kidney substance as in Beck's; second, in my method the muscular fibers are none of them cut, but remain intact and able to perform their functions as before.

NOTE.—After the publication of an abstract of this paper I received a reprint of an article published in the *Medical Record* by Dr. J. F. Baldwin of Columbus, Ohio. I had not heard of his method of anchoring the kidney and his article had been overlooked. My method is so similar to his that I am glad at this time to acknowledge his priority, though the method devised by me was entirely independent of his work along this line.

B. B. D.

## THE WORK OF THE DIGESTIVE GLANDS (PAWLOW) AND ESTIMATION OF PEP- SIN DIGESTION BY MODERN IN- STRUMENTS OF PRECISION.

FRANZ A. R. JUNG, M.D.

WASHINGTON, D. C.

One of the most noteworthy contributions in the line of investigations of the digestive process is without doubt Pawlow's recent book, "The Work of the Digestive Glands." It is originally written in Russian and translated into German by Dr. Walter, "Die Arbeit der Verdauungsdrüsen."

An English translation has not yet appeared; it may not, therefore, be out of place to mention briefly some of Pawlow's main achievements. He resorted to an original method of research by forming a sack from part of a dog's stomach, fastening it outside the abdomen and taking care to keep the innervation perfectly intact. Processes going on in the stomach could be observed in the sack without being interfered with by the presence of food. He found that there exists a perfect relation between the amount of food taken and the quantity of gastric juice secreted; the more food, the more juice.

The secretion of gastric juice and pancreatic juice

occurs in the form of a curve gradually increasing and then decreasing. The glands furthermore produce a juice of a different chemical composition with more or less pepsin ferment or with a variable amount of different ferments as is the case in the pancreatic gland. On the other hand, the degree of acidity of the gastric juice is constant and does not vary. Oscillations occur with an increased quantity of the juice and with neutralization by mucus. A specific action of the gastric glands is observed after a mixed diet as well as after feeding on a single article of food. This specific action pertains to the properties of the juice, to its quantity, its course and duration of secretion. After eating bread the juice shows the greatest peptic strength; next in order comes meat and at last milk. The so-called gastric bread-juice contains four times as much ferment as gastric milk juice and is four times as concentrated.

The acidity is highest for meat and lowest for bread. The hourly intensity of the work of the glands is about the same for milk as for meat and is much smaller for bread. But bread requires a longer time for work. A characteristic change in the properties of the juice takes place with every variety of food. Also a certain hourly process of secretion is observed to correspond to the kind of food ingested. With meat there is a maximum of secretion during the first or second hour, the quantity of juice being alike in both hours. With bread there is a maximum during the first hour, and with milk during the second and third hour. The juice is strongest during the first hour after meat has been taken, after bread during the second and third, and after milk it becomes strongest after the third hour. After bread a more concentrated juice is secreted, thus avoiding an increase of the quantity of the juice and thereby an excess of HCl. The total quantity of juice after bread diet is not much larger than after milk, but it is extended over a much longer time, so that the hourly amount of juice after bread is one and one-half times less than after milk or meat. HCl, as is well known, would prevent the conversion of starch.

In order to obtain pancreatic juice a piece of the duodenum containing the pancreatic duct was sewed into the abdominal wound.

The pancreatic juice varies like the stomach juice in regard to its quantity. It contains its three ferments in different percentages after different foods. Milk pancreatic juice has the largest amount of albumin ferment, whereas there is less in bread and meat pancreatic juice.

Amylolytic ferment shows the highest figures in bread juice, less in milk and meat juice. But bread pancreatic juice contains less fat ferment, while milk juice is rich in fat ferment. Meat pancreatic juice holds a medium position.

Vegetable albumin calls for the largest amount of ferment from the pancreatic gland as well as from the stomach, whereas milk albumin calls for little. The stomach pours a concentrated ferment over the bread, the pancreas a very diluted one.

Without any doubt there is a distinct adaptation of the juice to the food. Starchy food gets more amylolytic ferment and fatty food more fat ferment.

The next part of Pawlow's work shows that the nervous vagus possesses secretory fibers for the stomach and pancreas. At the same time, it also has an inhibitory influence. Pawlow proved furthermore that after cutting the esophagus and feeding the dog, a flow of gastric juice occurred just as if the food had reached the

stomach. This flow, however, did not occur after the cutting of the *nervi vagi*. If the dog with a cut esophagus is fed on stones, sand, acids, etc., no stomach secretion takes place. This proves that the appetite, the desire for food and the feeling of satisfaction during its consumption helps to promote the flow of gastric juice. This flow occurs even when the meat is only shown to the dog but is not actually swallowed by him. Appetite is the equivalent of a certain quantity of gastric juice at the beginning of the meal.

The continuance of the flow of gastric juice is not a simple result of mechanical irritation. Meat juice, bouillon and extract of meat proved to be powerful promoters of secretion, and to some extent even water had its influence. When bread or eggs are eaten without appetite, they lie like stones in the stomach without any digestion taking place. The appetite-juice is the initiative of the secretory process; this first juice produces the setting free of chemical substances contained in the albumin of the bread and has the same effect as meat extract, etc. Those extractive substances cause the further flow of gastric juice and finish the digestion. Fat diminishes the flow and the digestive power. Egg albumin alone and starch alone do not cause any secretion of gastric juice.

With the exception of the psychic secretion, the secretory work is a reflex act in which the promoters of secretion irritate the peripheral ends of the centripetal nerves. HCl causes the flow of the pancreatic juice by reflex action as soon as it appears in the duodenum. Starch does not stimulate the pancreatic secretion but increases the percentage of amylolytic ferment. Fat promotes secretion of pancreatic juice and increases the percentage of fat ferment. Sleep does not inhibit the action of the pancreas. Water produces a distinct secretion in the pancreas as well as in the stomach. Alkalies diminish the pancreatic secretion. Pawlow explains the action of amara (bitters) as appetizers. Table decorations, pleasant odors of the food, etc., are helpful as appetizers. Food as well as water must have a pleasing appearance, flavor and taste in order to cause psychic digestion.

Bouillon as a first course is the most important chemical promoter of secretion. Acid as medicine promotes pancreatic secretion. Milk is an exceptionally good food because it needs an extremely low degree of digestive work. Alkalies retard digestion, thereby producing times of rest for otherwise continually working organs.

Pawlow published about a year ago a second paper: "The Experiment as a Timely and Uniform Method of Medical Investigation." Again, he emphasizes the complete adaptation of the work of the digestive glands to the food. In regard to the salivary glands, he found that the mucin glands secreted a thin watery saliva with only traces of mucin upon the introduction of any indigestible substance, whereas eatable things caused the secretion of a more tenacious saliva with much mucin in order to make the food slippery. Further, the drier the food, the more saliva there is. Stones, ice water, etc., will not promote saliva. No purely mechanical or chemical stimulus will promote saliva. But give the dog sand or acids and large quantities of saliva will flow because the sand can not be swallowed otherwise and the acids will not be diluted without it.

Pawlow speaks of a psychology of the salivary glands. By sentiments, wishes and thoughts, often almost unconsciously, we influence the constant physiologic functions of the body. Water, acids, raw eggs and cooked starch

do not influence the flow of bile, but fat increases the amount of bile, as do the extractive substances of meat and the products of albumin digestion. The value of the bile lies in the fact that its addition doubles and triples the action of the pancreatic juice. It is especially the fat ferment which thus becomes strengthened. Bile stops the action of pepsin. Pepsin is dangerous to the ferments of the pancreas. Bile favors the action of the pancreas; it introduces the intestinal digestion. The juice of the smaller intestines proved to be an additional help to the action of the pancreatic juice; it increases the action of all the ferments, but especially that of the albumin ferments. The acid foods having passed the pylorus, produce by reflex a temporary closing until they have become neutralized. Those evacuation movements cease while the dog is actually feeding or has food shown him.

Catarrh of the stomach, experimentally produced by nitrate of silver solutions, showed a condition of asthenia and irritable weakness. The production of gastric juice was at first higher than normal and later on much lower. The average juice production was only two-thirds of the normal. The gland is made irritable and tires more readily. Pawlow recommends, therefore, according to his findings, the use of meat extracts and alkalies.

Before considering the results of Mett's method of determining the amount of pepsin digestion by means of capillary tubes, I would like to briefly mention the method of Hammerschlag: Fifteen grams of albumin are dissolved in 1000 c.c. of warm water and filtered. Then HCl is added until 100 c.c. contain 0.394 HCl (18 c.c. of HCl P.G. to one quart). Use two Esbach tubes, mix 10 c.c. of Hammerschlag's solution with 5 c.c. of gastric juice. Take 10 more c.c. of Hammerschlag's solution and mix with 5 c.c. of water. Fill each tube to the letter U; place the tubes for one hour in the incubator; then fill the tubes to the letter R with Esbach's solution; let the tubes stand for 24 hours. The difference in the amount of precipitated albumin corresponds to the amount digested.

Schüle, Gintl, Kövesi, Troller, Bachmann and Schiff have published their experience with this method. There have been several criticisms of this method, all of which have been repulsed by Schiff. Yet there is no doubt that the method can only have the value of an estimation. In cases of very feebly digesting juices, the presence of albumin in the gastric juice itself will give too high a figure, so that a weak digestive power will not be recognized. Schiff admits this.

The normal figures showing the percentage of pepsinogen with Hammerschlag's method and according to various authors are as follows: Gintl, 85-96 per cent.; Troller, 75.90 per cent.; Schiff, 60.68 per cent.; Schüle, 44.78 per cent.; Kövesi, 50.60 per cent. The opinion of Gintl in regard to the pepsinogen secretion is as follows: "A decided diminution of the value of free HCl to zero and even to negative values does not necessitate a similar condition of pepsin. With a deficit of HCl, there can yet be a comparatively high value of pepsin. He finds no characteristic pepsin secretion in ulcers, cancer, etc. Values from zero to normal may be found under these circumstances.

Kövesi finds between HCl and pepsinogen secretion there is no parallel. In sub- and an-acid juices, the quantity of the pepsinogen with few exceptions is smaller, but not quite proportional and adequate to the quantitative diminution of HCl. Destructive processes of stomach tissue influence the pepsinogen secretion less

than that of HCl. He finds the pepsinogen secretion normal in ectatic and atonic conditions but not in cancer. Troller says: In cases of chronic anacidity we can yet find a moderate pepsin and rennet production. Schiff considers that there is no parallelism between HCl and pepsin secretion. The latter is able to resist disease much longer than the secretion of HCl. In hypo- and ana-chlorhydria he finds no parallelism. His three cases of achylia gastrica simplex showed no pepsin digestion. In cases of cancer he always found severe diminution of pepsinogen production. In hyperchlorhydria he found normal, not increased values of pepsin. If we do not consider minor differences, we find that all investigators begin to realize that HCl secretion differs from pepsinogen secretion. The former is much more oscillating. We now speak of a pepsin question.

Pawlow's assistants do not make use of Hammer-schlag's method. They prefer that of Mett, which I wish to describe here in Pawlow's own words: "The methods used for analysis of the digestive juices were as follows: The albumin digestive power of the juice was tested according to Mett. This method has been perfected in our laboratory and has since been in constant use. Glass tubes with a lumen of 1-2 mm. are filled by suction with liquid egg albumin, which is then coagulated at a temperature of 95 C. Then the glass tube is cut into small pieces; these are soaked in 1-2 c.c. of the liquid which is to be tested. These preparations are placed for 10 hours in a thermostat at the temperature of 37 or 38 C. If the albumin dissolves, this process occurs at the two ends of the glass tubes. At the end of the 10 hours, one measures by the aid of a millimeter scale and a low-power lens, the length of the entire tube and the length of the column of coagulated albumin which has not been digested. The difference in numbers expresses in millimeters, or its fractions, the length of the digested albumin column. This method leaves nothing to be desired in facility of its use, objectivity and a precision of its results. Special experiments by Dr. Ssamojloff have shown that the digestion of the albumin columns within the first 10 hours by using the juices at our command, corresponded absolutely with the duration of the digestion proper. This was the case even if the juice had the greatest digestive power. This experiment weakens the very natural suspicion that the digestion of albumin in the glass tube could not take place with equal rapidity at the different depths of the tube, owing to the greater or smaller collection of digestive products filling the lumen. Consequently we obtain an accurate measure of the digestive power of the different juices by the length of dissolved albumin in the cylinder at the same given time.

Borissow in making his experiments in the laboratory of Professor Tarchanoff with this method clearly proved the underlying relation existing between the length of the digested albumin cylinder and the amount of pepsin contained in the examined juice. The following law resulted. In the digestive juices under observation the quantity of pepsin is like the square of the rapidity of digestion, that is, like the square of the millimeters of albumin cylinder, which were dissolved in equal time by the juices. We will illustrate this law by an example. If one juice has digested 2 millimeters and the other during the same given time, 3 millimeters, the relative quantities of pepsin of these juices are not expressed by figures 2 and 3, but by their squares, namely, 4 and 9. The difference is clear; according to the millimeter scale calculation, the second juice would

contain one and one-half times more ferment than the first; according to our law, however, in taking the square of the digestive numbers the second juice is two and one-quarter times stronger than the first. Naturally many experiments have been made with exact artificial pepsin solutions before deducting the above law.

Borissow arrived at his conclusions independently of Schutz, who had published before him his experiments, which, although entirely different, yet gave the same result. Schutz made polarimetric determinations of quantities of pepsin as resulting from the digestion of albumin. The absolute similarity of the results with such entirely different methods of investigation furnish a guarantee of the exactness of this law. Here I wish to express my regret that the method of Mett, although published and advocated as long ago as 1889, has not yet found the widespread use and appreciation which it so well deserves. How easily could it be made the universal method of determining albumin-digestive ferments, in order to make all experiments with these ferments capable of comparison, and no one will deny that this would be highly desirable.

With such a universal method, all juices of the different animals or men could be represented by a universal scale, and this might lead to important conclusions relative to the oscillations of ferments of different individuals, species and genera. We have yet to state that with Mett's method, the different diameter of the lumen of the glass tube is without consequence, and also that egg-albumin is of sufficiently stable composition to warrant its use as a test effect.

Linossier, who has examined the Pawlow-Mett method carefully to test its usefulness, considers it by far the best. He does not think the fine subdivisions of the scale into 0.01 mm. desirable, and prefers a scale indicating only 0.5 mm. Of the egg albumin he only uses the more liquid portion. For the closing of the glass tubes he recommends paraffin.

Roth allows the juice to work on the albumin for 24 hours. As shown above, Pawlow gives good reasons for preferring 10 hours; Schiff, therefore, criticises Roth's results, which are: average duration of digestion 4.5-5 mm. He does not agree with Pawlow and Linossier in pronouncing the method absolutely exact; yet he admits that it gives the best results. Oscillations of 2 mm. maximum are rare. His objection to Hammer-schlag's method is that differences of one-half pro mille can be the fault of the method as well as the result of correcting the digestion. With Mett's method 0.1 mm. shows digestion beyond any doubt. Roth also admits that the digestion is only, very generally speaking, proportionate to the quantity of HCl, yet there are cases of sub- and an-acidity with a comparatively better pepsin digestion, although Oppler states the contrary.

Roth found juices which surpassed the normal digestion. In three of his cases, this was the only pathologic finding to account for the dyspeptic symptoms. This author states that uncomplicated cases of hyperchlorhydria show no special increase of pepsin, yet two of his values for superacidity lie above the normal maximum. For purposes of therapy, Roth considers the method of Mett of importance. In order to improve the digestive values, he tried to give the normal acidity to the juices under examination, but he did not succeed in all cases and Schiff blames the method.

I would like to state here concerning the cases enumerated, that all figures of atrophic catarrh (7), all those of gastritis chronica (4) with only one exception

(3), all figures of carcinoma (15) with one exception (14), are either raised or not altered. All gastric crises are altered until correct (5), and in 17 atonies there are only 4 mistakes (13). I would say that in superacidity, we are not able by the mere addition of alkalines to raise or diminish the figures of pepsin. This corresponds to the recently discovered fact that the pepsin digestion need not correspond to the values of HCl.

Roth gave in 18 out of 94 cases Hammerschlag's figures, but he drew no comparison, and says that an accurate comparison can not be made since Hammerschlag's method is only one of estimation. I believe Dr. Schorlemmer of Berlin will soon publish a series of comparative pepsinogen estimation with both methods, which will serve to determine their relative value. For absolute precision and from a mathematical point of view the method of Mett must be considered a better one.

Pawlow says that the lumen of the tubes should be 1-2 mm. I have tested tubes of 4 different sizes and thought at first that capillary tubes with very fine canals would show a finer graduation. This was not so. The

These six random cases show that 1 mm. tubes give practically the same results as 1.5 mm. tubes. There was noticed, however, a difference in albumin only two days old and albumin one week old:

1.5 mm. 2 days old.

$$2 + 2 = 4$$

$$1 + 0.8 = 1.8$$

1.5 mm. 7 days old.

$$3 + 3 = 6$$

$$1.4 + 1.2 = 2.6$$

Dr. Schorlemmer of Berlin has constructed a suitable apparatus and allowed me very courteously to have it duplicated by Hermann Rohrbeck in Berlin, which kindness is hereby gratefully acknowledged. The advantages of this instrument are that one can both measure and cut with it. On the left is a knife with a scale underneath, enabling one to cut off pieces of exactly 3 mm., which after digestion has taken place can be measured on a graduated glass scale. The tubes are kept in place by a spring. In order to distinguish 0.5 mm. a lens of 2 or 3 times magnifying power is applied. I found it difficult to get always the best light on the scale, which also seems to be too short, being only 3 mm. in length. If it happens that a tube is a few

Good tube

Bad tube

following figures will show that tubes below 1 mm. indicate rather low numbers. The reason for this seems to be the difficulty of the outflow of the digested albumin. The area of a circle varies as the square of the radii:  $a : a = r^2 : r^2$ ; therefore,  $0.4 : 1.0 : 1.5 : 2.0 = 4 : 25 : 55 : 100$ .

A glass tube with 1 mm. lumen therefore has a capacity for outflow more than 6 times greater than a tube with 0.4 mm. diameter. On the other hand, a tube with 1.5 mm. lumen has only double the outflowing capacity of a tube with a 1 mm. lumen.

| 0.4 mm. lumen.      | 1 mm. lumen. |
|---------------------|--------------|
| 1st case 1.8 to 1.6 | 2.1 to 2.2   |
| 2d " trace          | 0.4          |
| 3d " 0              | 0.2          |

Then I tested tubes with apertures of 1 and 1.5 mm. The result showed that both worked practically alike:

| 1 mm.                  | 1.5 mm.         |
|------------------------|-----------------|
| 1st....1.6 + 1.8 = 3.4 | 2 + 1.4 = 3.4   |
| 2d....0 + 0 = 0        | 0 + 0 = 0       |
| 3d....1.8 + 1.8 = 3.6  | 1.6 + 1.6 = 3.2 |
| 4th....0.8 + 0.8 = 1.6 | 0.8 + 1.2 = 2.0 |
| 5th....3 + 2.6 = 5.6   | 2.6 + 2.8 = 5.4 |
| 6th....2 + 2 = 4       | 2 + 2 = 4       |

fifths of a millimeter longer than the ruler, the measuring on one side will not be correct unless one reverses the ends. Since the knife has always a slight inclination to oscillate it does not always cut off exactly a piece 3 mm. in length. In order to overcome this difficulty, I resorted to a simpler arrangement where the graduation is not made upon a glass slide, but upon steel, which is indestructible and can be cleaned. Furthermore, it is 5 cm. long, divided into 0.2 mm. and the scale is plainly visible by simply placing the tube into a rounded depression made for this purpose and reading the markings of both ends through a magnifying glass. I even use a simple steel ruler with 0.2 mm. graduation which I place on a black background and put the tube alongside of it. These instruments were made to my satisfaction by the firm of Messrs. Brown & Sharp Manfg. Co., Providence, R. I.

As soon as a glass tube filled with coagulated albumin has been opened, the atmospheric influences begin to work and destroy the solidity of the albumin column. It is necessary to use an egg albumin of equal consistency for filling the tubes. It ought to be either the more liquid part or the more solid part, care being taken

not to mix both in the same tube. The tubes should not be opened before they are 3 days old. They should be kept well closed at both ends either with cotton or rubber caps. Just before use, a tube is cut into suitable pieces, care being taken to use only tubes free from air bubbles. I prefer after all experiments a tube with a lumen of 1.5 mm., which shows, as we have seen, the same measurement of the digested parts and has the advantage over the 1 mm. tube of being more easily read. The larger tubes show sharper markings, because the digested portion of the albumin column can flow out more readily. This difficulty was well marked with 0.4 mm. tubes; if the edges are not sharp the albumin column has not been of equal consistency. The best tubes show 3 zones: 1, albumin, sharply cut; 2, a fine hazy cloud; 3, clear glass; or 2 zones: 1, albumin, sharply cut; 2, clear glass.

Two tubes are always placed into 0.5 c.c. gastric juice and the average digestion of both is taken as the result. A ruler of the finest graduation of fifths of millimeters being employed, the accuracy of measurement to millimeters and even half millimeters is guaranteed.

| 5         | 25            | 0.1          | ..        | 32           |
| 7         | 20            | 0.5          | ..        | 18           |
| 24        | 17            | 0.2          | ..        | 58           |
| 8         | 16            | 0.25         | 8         | ..           |

15 cases.

From the above list, the following conclusions are drawn:

1. The normal values for the pepsin digestion are, according to Mett's method, 5.5 to 5.9 mm. (List I and III.)

2. With Mett's method, sub- and an-acidity have lower values than normal or superacidity (1.9 mm. is the average). They do not reach the average values of superacidity.

3. The diminution of pepsinogen does not run proportional with that of HCl. Even with a deficiency of HCl, the value of pepsin can be higher than that of mild subacidity. (List II.)

4. Superacidity, generally speaking, has high and highest values of pepsin, yet there are cases of unusually high HCl figures with disproportionately low pepsin values. This points distinctly to a pepsin question. Large quantities of HCl after a Boas test breakfast do not always include a free secretion of pepsin.

5. According to the method of Hammerschlag, 60 seems to be the normal figure of pepsin secretion. (List IV.)

6. With Hammerschlag's method in opposition to Mett, the values of sub- and an-acidity reach the average of that of superacidity. The average values approach each other more with Hammerschlag's method.

5.5 Superacidity; 1.9 Subacidity Mett.

60 Superacidity; 45 Subacidity Hammerschlag.

7. Besides, with Hammerschlag, we see no proportion of the HCl diminution and the pepsin secretion in cases of subacidity. (List V.)

8. The methods of Hammerschlag and Mett show the same proportions in 66 per cent. of the cases. (Lists VII and VIII.)

9. In five cases out of 15 the two methods give different results. In Cases 6 and 23 it is question of normal and superacidity. Hammerschlag's figures do not correspond to the high millimeter readings but only show medium values. On the other hand, Cases 32, 13 and 14 have proportionately high Hammerschlag figures with low millimeter values. The corresponding HCl values are subnormal. In other words, in all those cases in which Mett's method differs from Hammerschlag's, the former seems to approach closer to the values of HCl. Generally speaking, this may be considered as an advantage of Mett's method.

10. It will be necessary in future to examine not only sub- and an-acid juices for their digestive strength, but also superacid juices which heretofore were considered as having *eo ipso* good digestive capacity.

## A VOLUNTARY BOARD OF NATIONAL EXAMINERS.

WILLIAM L. RODMAN, A.M., M.D.

Professor of the Principles of Surgery and Clinical Surgery in the Medico-Chirurgical College, and Professor of Surgery and Clinical Surgery in the Woman's Medical College of Pennsylvania.

PHILADELPHIA.

At the recent meeting in Washington of the Committee on National Legislation representing the American Medical Association, the subject of reciprocity between the several states was very generally discussed, and considered practically impossible with so many states and territories, each with its own standard and no two alike. More than half of the states were represented at the conference and the interchange of opinion was free. The committee appointed one year ago made a majority report through its secretary, Dr. Emil Amberg, advising against reciprocity, and in favor of a National Board of Examiners. The committee had, however, been working upon the hypothesis that such a board could be created and sustained by act of Congress. Letters read from Senator Burrows and others caused the committee to drop the idea of a national board created by act of Congress as such legislation would certainly be unconstitutional and in conflict with the several states. The states are sovereign and can not be coerced by the general government.

There is, however, nothing to prevent, or seriously in the way of a Voluntary National Board of Examiners, whose examinations shall be of such a character and high standard as to command the respect of the several states and cause them to issue license to any one who has successfully passed such an examination. To fail to do so, as was said by Professor William Welch in the discussion, would make such state ridiculous. I therefore offered this amendment to the report of the committee, which was promptly accepted and unanimously approved after full discussion. I then suggested that this board consist of six members, viz., the Surgeons-General of the Army, Navy and Marine-Hospital Service and three equally representative civil practitioners; two to be elected by the House of Delegates of the American Medical Association and one by the American Congress of Physicians and Surgeons. A seventh might be added to represent the National Board of Examiners. This board would at once have the confidence of the profession as it would be comprised of able men absolutely above suspicion. The time of

meeting should be from June 1 to July 1, so as to accommodate the graduates of all schools.

The examination should be both theoretical and practical. Applicants should be taken into the wards of hospitals and be given opportunities to make diagnoses and examine urine, sputum and blood, as well as outline courses of treatment.

The place of meeting should, as a rule, be in Washington; provided its hospital facilities are adequate. It is desirable, however, to vary the place of meeting from time to time so as to make the board truly a national one, and to subserve the interests of the greatest number of applicants.

The fee should be not less than \$25, or the maximum amount charged by a state board, so as not to bring the national into too great competition with any state board.

Now, what would be the inducement to graduates to go a distance, assume greater expense possibly than they now do, only to get a diploma which *need* not be recognized by the states? My answer is that as every state and territory in the Union now recognizes the commission of medical officers of the Army, Navy and Marine-Hospital Service, so they would be glad to recognize the certificate or diploma of any one passing an examination conducted by able and distinguished men representing all sections of the country. A man with such a diploma should be permitted, like the Constitution, to follow the flag and practice medicine and surgery anywhere within our possessions. Now, if a man moves from Pennsylvania to New Jersey he must pay \$25 additional for the privilege, and in other states pass another examination as well. This is manifestly unfair to men who are excellent practitioners, but necessarily rusty in the theoretical branches, such as anatomy, physiology, chemistry, etc.

There would be another inducement to young men to appear before the national instead of a state board: there are many positions within the gift of the federal government, such as contract surgeons in the Army, Navy and Marine-Hospital Service; physicians to Indian agencies and members of pension boards of examiners in all parts of the country, requiring the services of more than average men. Any one holding the diploma or certificate of such a national board would at once have the advantage over any one else less fortunate. In truth, in nearly all such cases, a further examination could, with perfect justice to the government, be waived. So manifest are its advantages that each year there would undoubtedly be a larger number of applicants; and in time sub-boards would be necessary to accommodate the number applying—each to meet in some large city with abundant hospital facilities and accessible to many applicants.

There is but one serious question involved, and that is whether or not the expenses of such a board could be met for a year or two out of the fees of applicants. There would be only three or four examiners to pay, as I was told by each of the Surgeons-General that they would act, or detail some one from the service, gratuitously.

There is also, I take it, little doubt that suitable quarters for conducting the examinations could be furnished by the bureau of health which is almost certain to be established by this Congress.

Should the fees be insufficient to secure the services of the best men, the American Medical Association could well afford to pay for the two members appointed by it. Certainly, this great organization, with money in its

treasury to spare, can well afford to give something to a cause having behind it the best elements in the profession. It is unfair to ask that any one worthy of the appointment as examiner should give a month, possibly longer, to even so excellent a cause without compensation. So could the American Congress of Physicians and Surgeons provide, if necessary, for its appointee.

A voluntary board is better for the profession than a compulsory one, for its standard can reasonably be made higher, and its certificates be a diploma *cum laude*. Moreover, the profession will be elevating and purifying itself and not trusting to legislation to accomplish the purpose which under our form of government is impracticable, even though it were desirable.

I have little doubt, however, that the fees would be sufficient to pay the examiners well even the first year. If the examinations should be held in Washington it would be very accessible to all of the eastern schools, representing, we will say, a thousand graduates. There will be more, as Philadelphia alone has each year about 400. The eastern schools are of such standard that they would encourage their graduates to go before the Voluntary National Board, and it would be safe to count upon 10 per cent. (100) of the graduates of Washington, Baltimore, Philadelphia, New York, Richmond and Charlottesville (University of Virginia), and other cities adjacent to the capitol doing so. Twenty-five hundred dollars should thus be assured; the expenses would be nominal and all over and above expenses would be divided between the three examiners. I am informed that the officers representing the three public services would be estopped from accepting compensation. This 10 per cent. could be probably doubled by the board meeting in Washington a week, and then spending a week in each of the three large cities adjacent to it, viz., Baltimore, Philadelphia and New York. The medical schools in these cities would willingly furnish quarters and facilities for conducting the examinations, and the hospitals furnish all necessary clinical advantages. This plan has been unanimously endorsed by the delegates from the several states meeting with the Committee on National Legislation and will be recommended to the House of Delegates at the coming meeting of the American Medical Association. It is to be hoped that it will be carefully considered and either it or a better plan at once inaugurated, as something should be done to encourage a higher and better medical education and to give in return something in the way of privileges and professional standing to those possessing it.

## THE NEUROLOGIST'S ART.

JOSEPH COLLINS, M.D.

Professor of Nervous and Mental Diseases in the New York Post-Graduate Medical School.

NEW YORK CITY.

Knowledge is an excellent drug.—Montaigne.

There is a widespread belief that the recognition, interpretation and treatment of diseases of the nervous system offer peculiar obstacles, and that many of them are entirely unamenable to therapeutic measures. Now and then it comes to the ear of the neurologist that when he has made the diagnosis his usefulness ends. It is often said, half in jest but more in earnest, "To what end is all your diagnostic acumen and your skill in differentiation when your prognosis is so gloomy?"

The physician who has had wide experience in the treatment of nervous diseases knows that there is no

ground for these calumnious imputations. He knows that diseases of the nervous system, organic and functional, yield as readily to therapeutic measures as the majority of functional and organic diseases. He knows that if the same care, perseverance and skill are brought to the patient suffering from nervous disease that is bestowed on the victim of other and comparable bodily diseases that the results of treatment will be quite as satisfactory.

#### NERVOUS DISEASES CONTRASTED WITH OTHER DISEASES.

To bring the truth of this home to those who have been burdened with the belief that neurological therapeutics is a myth and that the neurologist is therapeutically impotent, it is only necessary to contrast the results of the neurologist's work with that of the physician who devotes himself to internal medicine. How much does therapy avail in the curative treatment of any kind of hepatic cirrhosis? With what degree of confidence can one say to the sufferer from cholelithiasis after an operation for gallstones that medical treatment and régime will prevent the reformation of calculi? In what measure has the prognosis of the different forms of Bright's disease and of the various degenerative cardiopathies been altered by therapy in the last generation? Are we more successful in combating gout, arthritis deformans and psoriasis than were our forefathers? These are not the interrogations of one who has been made morbidly sensitive by the imputations that are sometimes cast upon the branch of the therapeutic art that he has espoused, but a simple catechism to show that the neurological therapist has as much right to be optimistic as has his brother practitioner. That there are some diseases of the nervous system that are quite beyond the reach of all therapeutic measures everyone must admit. Such are general paresis, syringomyelia and paralysis agitans, but these are uncommon ailments and they constitute an extremely small proportion of the diseases that come within the neurologist's scope. Nor should the incurability of such diseases make our attitude toward them one of complete despair and therefore unworthy the effort of seeking for something in nature or in art that will successfully cope with them. One must pursue the search for an adequate remedy just as assiduously as he does for means of combating infantile diabetes, pseudo-leukemia, Addison's disease, pemphigus or any of the other diseases that still resist treatment. Face to face with any of these diseases there are few who can reconcile it with their consciences and their sense of duty to fold their hands and do nothing. That there are some who do this I know, but they do not accord with my own conception of the best type of physician.

The study of medicine as an abstract science has done much to give it the high position that it holds amongst the sciences, and such study should be encouraged, but the duty of the general practitioner is the treatment of disease. Because a disease has been found in his inherited or acquired experience, to pursue its course to a fatal end, there is no valid reason why he should not bend every effort to the determination of means that shall shape its course otherwise. In this way alone the value of thyroid feeding in myxedema, arsenic in leukemia and quinin in malaria was determined.

The attitude of great neurologists at the zenith of their career toward therapeutic possibilities has always seemed to me particularly inspiring and I recall the closing words of an address on neurological therapeutics a few years ago by Sir William Gowers: "I have been surprised at the amount of good that can be done in

affections commonly looked upon as intractable—relief, arrest, restoration. With each successive year's experience it seems to me greater and more distinct and to elicit more gratitude from the patients to whom it is applied."

#### THE NEUROLOGIST'S ART.

Does the physician especially trained in the recognition of nervous disease enjoy any special privileges which lead to such conclusions? I think not. Wherein, then, lies the neurologist's art?

1. In recognizing that the vast majority of diseases that he encounters can be influenced by treatment.

2. In having in his mind, when face to face with disease whose course he desires to influence favorably, a clear picture of the pathological process constituting the basis of the disease.

3. In appreciating that the successful treatment of nervous diseases requires the most scrupulous attention to detail in the application of measures that experience has shown to be of value.

4. In utilizing judgment and skill in the selection and application of measures that have been found useful, empirically and experimentally.

5. And finally, in realizing from the outset that a disease or disturbance of function which is either the expression of a prenatal defect, or of many years' duration can not be overcome in a few weeks, or even a few months of treatment even though the hand that administers it be both masterful and magical.

You will remark that nothing is said of a knowledge of human character, of the possession of tact and an unlimited fund of sympathy, of personal determination tempered with a full recognition of human limitations—these constitute the neurologist's endowment, not his art.

#### THE CURABILITY OF NERVOUS DISEASES.

To prove the first proposition, viz., that the majority of diseases encountered by the neurologist are susceptible to treatment that will cause cessation, amelioration or cure of the disease process, it might be necessary, if my auditors were hostile to the acceptance of this proposition, to cite individual cases, and numbers of them, but this being not the case it is necessary only to state the proposition and to reiterate that the treatment of diseases of the nervous system is no more the cultivation of a barren acre than the treatment of disease of other systems of the body.

Failure to conform to the tenets of the second proposition, i. e., to have in mind a clear picture of the pathological process which one wishes to overcome is responsible for many failures in the treatment of nervous diseases and for the unscientific way in which such treatment is often instituted and carried out. In no other way than conforming to it can one gain a clear conception of the limitations put upon one's efforts by nature. For instance, in the treatment of one of the common organic diseases of the nervous system, locomotor ataxia, one can not possibly conceive of the usefulness of galvanic electricity to the spine, the administration of strychnin, the utility of the system of exercises and mental gymnastics known as the Fraenkel movements unless he knows that the anatomical basis of the disease is a primary, slowly progressing decay of the posterior spinal roots beginning in that segment of their distribution which is between the spinal ganglia and the posterior columns of the cord and extending peripherally and centrally, but particularly in the latter direction until finally their intraspinal representation is quite wiped

out, constituting so-called sclerosis of the posterior columns. If it is not recognized that this process is primary, one may be tempted to employ measures that might be supposed to influence the process to which it is secondary. Indeed, ergot was formerly given in this disease with the hope that it would, by exercising its physiological effects upon the blood vessels of the spinal cord, cause a lessening of the vascular condition to which the degeneration of the posterior columns was thought to be secondary. To-day we hold that ergot is injurious in the treatment of tabes. Mercury and the salts of iodine given in doses sufficient to act as an antisyphilitic are in the same category. Although four out of every five cases of tabes occur in persons who have had syphilis, and although there seems to be no doubt that tabes would practically cease to exist if syphilis could be wiped off the earth, still the morbid process constituting the disease has nothing of a syphilitic nature in its constitution, nor are there any evidences that there has been at any time in the course of the disease any pathological process which could in any way be construed as syphilitic. If the physician who encounters cases of tabes but rarely, and who can not therefore be very familiar with the disease practically were to have this in mind one would see less often tabic patients in whom symptoms of the disease had been accelerated by the vigorous administration of anti-syphilitics.

In what other way can the great importance of absolute rest, of the administration of medicines that contribute to it, and of the application of ice-bags to the spine in acute anterior poliomyelitis be conceived of than by having in mind a distinct picture of the exudative, destructive inflammation going on in very perishable structures, viz., the cells of the anterior horns of the spinal cord and which will run its course in a few days. Yet I venture to say that in comparatively few cases are these measures instituted. If they were the results I believe would be evidenced by milder sequelæ of the disease. The same may be said of the treatment of Sydenham's chorea. The majority of cases are treated by the administration of arsenic, quinin, antipyrin, or whatever so-called anti-choreic is in vogue at the time or is being puffed most in the journal that the practitioner reads. Yet that same practitioner would not treat a case of rheumatism by giving the salicylates alone without saying a word about the dietary, about the necessity for alkalinizing the excretions, for rest and retirement until the acute manifestations of the disease had passed. Chorea is a rheumatic, infectious disease of the blood which causes in turn a functional perversion of the cerebral cortex, principally the motor cortex. This perversion of function is manifested principally by the conspicuous symptom of the disease—dance movements. Rarely has the disease any organic basis, but when it has it consists of a slight encephalitis. The blood disease of which it is an epi-phenomenon results from infection just as rheumatism in the majority of instances is an infection due to divers but particular organisms as shown by the researches of Poynton and Paine.<sup>1</sup> Achalmé,<sup>2</sup> Riva,<sup>3</sup> Apert and Triboulet,<sup>4</sup> to mention no others, to be a self-limiting disease. The most important feature in the treatment of chorea is rest and if this can be secured medication is rarely necessary. In fact, whatever medicine is given is with a view of securing rest and of overcoming the impressions made upon the blood by the acute disease. For instance, exalgin, one of the

most reliable anti-choreics, owes its efficacy entirely to its capacity to cause motor sedation. It does not seem to me that further emphasis or illustration is needed to carry this point, but if there were we could cite no better illustration than the successful treatment of neurasthenia based on a conception of the pathogenesis of that neurosis.

#### DETAIL IN THE TREATMENT OF NERVOUS DISEASES.

More important than everything else in the successful treatment of nervous diseases is conformation to the principles of my third proposition, viz., that successful treatment requires the most scrupulous attention to details in the application of the measures that experience has shown to be of value. I venture to say that in nearly every instance in which the general practitioner fails to get as satisfactory results from the treatment of any nervous disease as the neurologist, the failure can be traced to neglect of this cardinal principle. If I have interpreted aright the impressions received from an extensive acquaintance and intercourse with general practitioners as represented by my classes in the New York Post-Graduate Medical School, the failure to get gratifying results in the treatment of even the commoner neuroses is directly due to the fact that they pin their faith to specifics—of which by the way there are none in neurology—and expect everything from the administration of medicine. A patient comes under treatment for epilepsy. In nine cases out of ten the physician contents himself, I fear, with writing a prescription for a mixture of the bromid salts and in giving some perfunctory directions concerning the diet, particularly the consumption of meat. The result in the vast majority, in fact practically in all cases, is most unsatisfactory to the patient and physician alike. How could it well be otherwise in a disease in which the moral and hygienic treatment, including diet, discipline, education, occupation and recreation, are of far greater importance than the medicinal treatment. It has been demonstrated again and again that in nearly every case of epilepsy the number of attacks can be reduced one-half by conformation to these requirements. Whereas, if they are neglected and the bromids alone are relied upon, no such results follow.

In the same neurosis how often is care taken to determine the dose of the one real anti-epileptic drug, the salts of bromine? It is quite impossible to say what the dose of a bromid salt should be before considerable experimentation is made. There is no more dosage of bromid according to weights and measures than there is of alcohol for a patient with typhoid fever. The dose is the amount the patient can dispose of. For one patient it may be a scruple twice a day, for another it may be a dram or two drams; it is necessary to make an individual study of each case. It is as ridiculous to say that the dose of bromid for an epileptic is 20 grains three or four times a day as to say that the dose of quinin for a patient with malaria is 5 grains three or four times a day.

If what I have been saying about the necessity for precision and particularization is true for the treatment of epilepsy it is much more true for the treatment of neurasthenia, hysteria, sciatica, tic douloureux and a number of other functional diseases, particularly those which consist in, and depend upon primary alterations in the molecular nutrition of the nerve elements, manifested by disturbance of their function, either transient, or so persistent as to imply alteration of structure, i. e., the functional and nutritional diseases.

1. *Lancet*, Sept. 22 and 29, 1900.

2. *Annales de l'Institut Pasteur*, 1897.

3. *Centralblatt f. Innere Med.*, 1897, p. 825.

4. *Comptes rend. Soc. de Biol.*, 1898, vol. v, p. 128.

Is it probable that so many cases of sciatica would become chronic, and so many victims of this disease be incapacitated if the same care was meted out to them when they are acutely ill as they would receive were they ill of pneumonia? Here again the attitude of the practitioner often conveys the absurd belief that there is some specific called the salicylates, gaultheria, turpentine, aconitin, gelsemium or what not that will battle with this disease of divers and multitudinous causation and hurl the diseased nerve, sheath, or functionally perverted fibers back to health. Is this not an appalling absurdity? It is like treating all cases of lameness by fitting each one out with boots for flat feet and expecting recovery. One out of twenty perhaps will recover, for that may be the proportion of lameness that is due to flatfoot, but the other nineteen must go elsewhere for relief. The case of the patient suffering from sciatica is exactly a parallel one. Particularization is the first requisite in the treatment, then precision in the application of the particular indication for treatment.

The necessity of attention to detail in the successful treatment of nervous disease is never so apparent as in the treatment of that mysterious disease which we call neurasthenia and which consists in an acquired, or an inherited and acquired enfeeblement of all the nerve centers, the clinical picture varying as one set or another of such centers manifest the weakness most conspicuously. In one case the emotional side of the individual's make-up is most upset, in another the mental side, in a third the spinal centers, sometimes the sympathetic centers, but usually features of all these appear in the clinical picture, which is too familiar to you all to necessitate a verbal sketch. It is a species of disease that causes as much mental and physical misery as one can readily imagine and to encompass its cure, deep study, careful thought, tact, perseverance and untiring care are required. I suppose that there are few diseases that the rank and file of practitioners treat with less satisfaction. And yet, save in the rudimentary forms, that is to say, in the forms founded on an inherited disequilibrium of the nerve centers occurring early in life as an expression of this prenatal deficiency, and not the variety dependent upon exhaustion, intoxication and stress, it is not a difficult neurosis to cure if one attacks it with the same determination and treats it with the same scrupulous care and watchfulness that one gives an attack of typhoid fever or of gout.

#### MERIT OF THE REST TREATMENT—EFFICACY OF DRUGS.

It is in such care that the merit in great part of the so-called rest treatment, properly carried out, lies. Mere drugging is not sufficient. To treat such a case satisfactorily one must use all those non-medicinal agents, of which we shall speak further on, that make for the elimination of injurious products from the system, for constructive metabolism, and for the production of neural energy and functional equilibrium. The most that we can expect drugs to do in such a case is to aid in overcoming contributory causes of the disease, such as auto-intoxication, and to assist the secretions and the excretions. Drugs do not cause or even assist materially constructive metabolism, the one all-important element in the restoration of health, but massage, hydropathics, rest, food, exercise and mental suggestion do. The use of these in systematic fashion, according to rule and method, subject to variation for the individual, not in a haphazard and desultory fashion cures them all unless the condition is so ancient that structural change which knows no restitution has taken place. The failures that result when such treatment is essayed are more

often to be laid at the door of the patient than of the physician, for in my own experience these are the cases in which treatment has not been thoroughly tested. I have rarely had impressed upon me so strongly as in a recent experience the apparent antipathy which some of us have to the necessity of conforming to details in the treatment of cases in which the results of assiduous treatment do not seem to be readily apparent. We all know what a sad picture the patient with the remains of anterior poliomyelitis presents. Everyone who has treated many of these cases believes that persistent treatment contributes a little to the restoration of function and the preservation of some of the muscular fibers in the atrophying part. Every little gained counts so much. I saw in the early part of the present season a child 4 years old who had had, nine months before, a mild attack of anterior poliomyelitis which had as a result an atrophied, paralyzed left leg with compensatory deformity in the right foot. She was put under careful treatment consisting of daily intramuscular injections of nitrate of strychnin beginning with 1/100 grain and increased up to 1/20 grain, massage, as much resistance exercises as possible, faradic electricity and local warmth by means of flannel covering of the leg during the day and repeated artificial warming and dry heat at night. At the same time she was sent to an orthopedic surgeon who fitted her with braces. In six weeks there was very perceptible improvement. I wrote the family physician (who by the way had not sent the patient to me) telling him what I had done and expressing a hope that he would see fit to carry out some such treatment when the child returned home, as it had been shown to be of such service. Fearing that the dose of strychnin might seem to him rather large I said that 1/40 grain seemed to me about the proper dose for him to give. A few days ago I got a letter from the mother of the patient saying that the doctor told her that he could not find it in his heart to kill her child with strychnin as I had advised him, that he would give her a pill of 1/100 grain and that she could buy a battery and use it herself, and that the child "would grow out of it." That represents a keen perception of the necessity for detail in the treatment of nervous diseases and a fine effort to conform to it. I am sorry to say that I could recount a number of similar experiences.

#### THE USE OF NON-MEDICINAL MEASURES IN TREATING NERVOUS DISEASES.

Skill in the selection and application of measures that have been shown experimentally or empirically to be serviceable in the treatment of nervous disease is a large part of the neurologist's art. These measures include not only drugs but massage, electricity, the external use of water, mental suggestion, rest and occupation, exercise, vibration and a number of other means. I am a believer in the efficacy of drugs and I await hopefully and confidently the discovery of means to combat all the ills that man suffers, even though he be not heir to them. I believe that Nature provides an antidote, if it can be discovered, for every ill that art inflicts and that the highest known form of evolution should have its final transformation at three-score years and ten into another form of energy by a process of natural decay and not be disease. While anticipating this discovery and assisting in the search we must do the best we can with the means at hand. Drugs constitute one of these means. The measures enumerated above constitute far more important ones and, in my experience, it is a working familiarity with

them that the general practitioner often lacks and not skill in the use of drugs. Therefore I shall devote my attention to a brief consideration of some of these measures. I appreciate fully that nothing particular can be said of them in an address of this scope.

#### THE THERAPEUTIC VALUE OF ELECTRICITY.

Two of the most useful measures in the treatment of nervous diseases in my experience are massage and hydriatics: two of the least useful are electricity and hypnotism. Many hold the reverse of this. But they base their opinions, I fear, on the frequently repeated statements of a few who never offer satisfactory substantiation of their statements. I am far from denying the therapeutic value of electricity in the treatment of nervous diseases. Its value in facilitating restoration of integrity and function of inflamed nerves, such as in peripheral facial paralysis, lead palsy and other forms of neuritis, can not be gainsaid. It is also of some service as a pain reliever and an excitant of sluggish muscles. Neurological therapeutics would be deprived of much if electricity were taken from it. That which I am endeavoring to maintain here is that electricity is not a curative agent of great importance and compared with hydriatics and massage it is of small value. The best proof of this I think is that neurologists whom I have seen at work and with whom I have been at some pains to talk, use it very little as a therapeutic measure. As an aid to diagnosis and as a means of estimating the prognosis of diseases of the nerves and muscles it is of great importance. That this view is not shared by general practitioners is amply testified to by the batteries in various stages of decrepitude that can be unearthed in their offices. It would be interesting indeed to learn if they, as the supporters of the battery-making industry, can show results in the shape of amelioration or cure of disease to justify the expenditure. When I talk with general practitioners on this score they usually inform me that although they have one or more batteries (which, as a rule, are not in working order) and that they have used electricity frequently they do not feel that they have the skill in applying it or the requisite experience in its use to justify them in expressing an opinion. I feel that they are too modest because the only skill which is needed is a knowledge of the elementary principles of electricity as a force and which is taught in every high school. Professors of the art do not know more. It requires no more skill to give electricity therapeutically than it does to give digitalis. The skill is displayed in knowing when to use it and what to expect from it. The former is taught in every text-book on medicine and nervous diseases, the latter I am making an effort to put before you.

#### THE FIELD OF HYPNOTISM.

Hypnotism is another agency used in the treatment of nervous diseases that could be spared and never missed. Yet that which is at the basis of hypnotism and the entire superstructure around which it has been built is the very essence of the neurologist's art, as it is of every therapist. That something which makes the real physician a whole sun of illumination and a Gibraltar of hope to the despairing invalid is the subjective condition of the patient which markedly favors the operation of anything that the physician may do or say. Thus comes the immediate mending that follows reassurance, the uplifting that hangs on an assuring grip or an encouraging glance. It is this state of favorable subjectivity that so-called hypnotism causes. Purposeful suggestion accomplishes that which the physician does *secundum artem*. In so far as we are con-

cerned as therapists there is nothing in hypnotism that transcends ordinary human understanding or that necessitates flight to the occult or mysterious for its comprehension. Yet I venture to say that nine persons out of ten do not take this view of it. I would not be understood as saying that the phenomena of hypnosis from a physiological and a psychological standpoint are fully comprehended, but they are quite as well understood as that of normal sleep, and who thinks nowadays of standing half in wonder, half in awe, before a sleeper, even though the sleep has come to him while his attention is fixed upon one who is laboring to save his soul and telling him about it in a droning monotonous monologue. Yet this is the feature of the hypnotic performance that fills the spectator with awe, and perhaps with a little of the feeling that the person who can accomplish it must be more god than man. I do not tremble for my reputation as a prophet when I say that the day of the hypnotist—i. e., one who allows it to be believed that he is endowed with a peculiar and supernatural possession and whose manner of using it, weird and bizarre, can contribute only to such a belief—has passed. The memory of it, however, remains and many unfortunately refuse to avail themselves of the aid that it offers in the treatment of both functional and organic nervous diseases because of the stench of charlatanism that still clings to it. One word more on this subject. I have many inquiries, personal and by letter, as to where the art of hypnotism may be acquired. You have all seen the pictures and the addresses of those "professors" who are willing to teach it for a consideration. Mental suggestion as a therapeutic aid can be acquired just as a well-modulated voice, a pleasing address, an assuring expression, or any other element of a successful "bedside manner," but the more it is artificial and borrowed from another the more worthless and useless it is. The physician who is able to gain the respect and the affection of his patient will never know the need of hypnotism, and if Nature has not endowed him with the qualities to do this he might as well pray to St. Anthony for them as to hope to learn from a professor.

#### THE USE OF WATER: AN ESTIMATE OF ITS VALUE.

Does anyone deny that water of different degrees of temperature applied to the surface of the body is beneficial in almost every disease attended with lowered vitality and impaired nutrition? I think not. Then why is it not more universally used? When I ask this question of my friend the family doctor he usually responds "because I haven't got the apparatus and because I do not understand the technique of its application." Although I tell him that to obtain most of its beneficial effects scarcely any apparatus is necessary, and that the technique can be acquired by a little experimentation upon himself and his patients, I fear that his future conduct does not convey flattering testimonial to belief in my veracity. Still I go on trying to promulgate the view hoping, like the patent medicine vendor, if I say it often enough and conspicuously enough that someone will believe it. If one can have the conveniences of a fully equipped hydriatic establishment or the services of a nurse who has had much experience in giving douches, packs, ablutions and tubbings, it is very agreeable. It is also very agreeable to have some one to make your night calls. But because you have not this assistance the patient does not have to lie in suffering all night or the woman complete her labor unattended. I maintain that the most successful application of water in the treatment of nervous diseases is an art that can be ac-

quired only by experience. But in this does it differ from any other branch of therapeutics? Not at all, and I know of no other way of acquiring the experience than by going hard at it. With a number of treatises on the subject in every language, with full consideration of the subject of hydriatics in every book on nervous diseases and therapeutics the earnest seeker after knowledge should have little trouble in possessing himself of all the experience that an adept can hand over to a novice.

#### MASSAGE AND THE OPERATOR.

Massage does not occupy a very exalted place in the therapeutics of nervous diseases, nor does it have, needless to say, any specific action in counteracting pathological states of this system. But in many diseases it is one of the most valuable agencies that we possess. For instance, in the treatment of hemiplegia there is nothing that compares with it. It is one of the indispensable auxiliaries in the treatment of neurasthenia. It can rarely if ever be dispensed with in the treatment of neuritis, single or multiple, anterior poliomyelitis, or certain forms of progressive muscular atrophy. Indeed it is one of the most important of the non-medicinal measures: hydriatics, electricity, exercise and dietetics. The fact that it requires no apparatus or paraphernalia for its use and that any intelligent person can soon acquire the dextral proficiency, providing he has the strength necessary for its application, is one of its leading recommendations. The professional masseur, and his feminine counterpart who has so often used it as a mantle to pander to vice are largely responsible for the disrepute of massage. We may congratulate ourselves that we are not responsible for its unmerited disuse as we are. I am afraid, for hydrotherapy.

A professional masseur who endeavors to impress his patients with his superior knowledge, resorting to clap-trap means for this purpose, may be a good rubber but he is a most undesirable person to have about a nervous patient and not infrequently has an unwholesome effect which offsets the benefit that follows the rubbing. The mode of applying massage is not all-important, as the graduates in the art maintain that it is, although naturally there is a right way and a wrong way. If one has in mind what he wishes to accomplish by massage he will have no difficulty in applying it himself or teaching any fairly intelligent person of strength how to use it. Its usefulness is restricted to quickening the lymph and blood circulation, to stimulating tissue metamorphosis, secretions and excretions and combined with passive motion to the prevention of adhesions. To accomplish these one makes use of stroking, frictions, kneading and tapping and it depends entirely on what one wishes to accomplish which of these he will use. My message to you particularly is, however, that massage is not a mystery and that although men and women are still being humbugged into paying large sums of money to learn it, and dishonest men and knaves are quacking with it, it is still a simple mechanical process whose use enables your patient to consume and assimilate the enormous quantities of food required to build up bodily tissues and repair bodily strength, which is the basis of cure in almost all cases of chronic invalidism, especially, of the functional variety.

#### THE PATIENT FIRST; THEN THE DISEASE. WORKING OVER THE PATIENT.

I have had a great deal to say about the individualization of therapeutic procedures because I think it is too much neglected. At the same time I have not forgotten that after all it is for the individual patient that

we should reserve our keenest discernments. Scarcely any two cases of functional nervous disease can be treated in the same way. This is particularly true of neurasthenia which forms such a preponderance of the functional nervous ailments as seen by the general practitioner. Although there are certain requirements that must be conformed to in every case, such as getting the patient out of the immediate environment in which she has developed her symptoms or had her evil habits fostered by over-zealous relatives and friends (which by the way does not necessarily mean sending her away, except perhaps to a neighboring boarding house or hotel), and the selection of a suitable nurse who is able or can learn how to give massage and hydrotherapy, even the method of accomplishing these and carrying them out is subject to much variation. But no two cases can be treated in exactly the same way, even with the non-medicinal therapeutic measures. And to the extent of determining just what means must be adopted to bring about desired results a certain amount of experimentation must be made with each patient. It does not contribute to the patient's comfort or well-being to share in this knowledge. For instance, one patient stands every form of hydrotherapy most indifferently. Another can not abide electricity, and so on. This being the case, one easily sees what would result if every patient were subjected to routine treatment without any variation. It is this study of the individual that enables the physician to interpret the case psychologically just as an examination and consideration of his various tissues and organs allows him to interpret it physiologically.

These fragmentary remarks would ill-represent the writer's attitude toward the treatment of disease if something were not said of that all-important element in neurological therapeutics—working over one's patient: working untiringly, hopefully, full of confidence that reward will be he vouchsafed in the shape of partial or complete restoration, even though manifestations of it be despairingly delayed. This was the art of that great master of therapeutics, the younger Seguin, to whose memory I respectfully make my homage. One could not watch him toil painstakingly with a case of peripheral facial paralysis, of epilepsy or of Grave's disease, day by day and month by month without becoming possessed of the belief that here was one at work who knew wherewith he toiled and whereof he builded. The success that rewarded him in the treatment of nervous disease justified his labor and his determination, and the lesson should not be lost upon us. The physician who thinks to balance the sympathetic nervous system manifesting the symptom complex of angio-neurotic edema or erythromelalgia with a few doses of strychnin or by regulating the functions of the alimentary canal, deserves commiseration, for life has in store for him but a succession of disappointments. The individual who believes that any disease save the self-limited diseases, can be dislodged after a few more or less desultory encounters, as the devil was dislodged in mediæval times by priestly exorcisms, should be labored with as patiently as the missionary labors with the heathen, that he may see the error of his ways, and come into the fold of the righteous.

#### OUR LIMITATIONS.

Finally, a word must be said concerning the importance of our 5th proposition, viz.: Realization that a disease which is the expression of a prenatal defect, or of many years' development can not be overcome in a few

days or weeks. This I am sure is generally conceded, but I am not sure that our conduct of the cases is always in keeping with our convictions. It is often necessary for the patient to appreciate it as keenly as the physician. A patient seeks relief for the symptoms of that mysterious neurosis known as exophthalmic goiter or Grave's disease. She may complain only of palpitation and a feeling of agitation, symptoms that seem to her trifling, and she expects relief from them as she would from cough or headache. The fact that she has a nervous organization that is congenitally unstable and that for years she has been poisoned by depraved secretions of the thyroid gland is entirely unknown to her, but she must in some way be made to appreciate it before she will take kindly to the tiresomeness of treatment. How else will she be reconciled to lying on her back for from one to three months suffering what seems to her the cruelties of the rest treatment with its concomitants of overfeeding, massage and electricity. But if she can be made to appreciate what her disease stands for and the natural way out of it how much easier it is for us to assist Nature in restoring her to health. This is not only true of Grave's disease but of almost every disease of the nervous system.

Another very necessary thing for us to do in our battle with nervous disease is to recognize limitations. The real nerve tissue, the parenchyma of the nervous system, the nerve unit or the neuron once destroyed is never regenerated. In this respect it does not differ from other specialized tissue cells. No one expects new liver cells to grow or new muscle cells to spring up to take the place of old. Nerve cells may, however, undergo much integral change before they decide to give up the ghost, and inherent and functional restitution occurs in nerve tissue that has been the seat of very decided alteration. Although our hands are not infrequently tied from the start in our encounter with nervous diseases, by virtue of the death of neurons, this should be by no means the signal for despair and retreat. We may find plenty of opportunity in saving other neurons from decay and in delaying the process in those that are fated to die. Let us take, for instance, locomotor ataxia. A man comes to us when he is 40 years old with symptoms that indicate the beginning of the disease. It is almost absolutely necessary that he should know the nature of his disease in order that he may avoid experiences that are bound to be injurious, and that he may cooperate with the physician in delaying the disease process. Although the outcome of tabes has not been altered by our present-day therapeutic resources it is beyond question that its course is materially delayed by treatment. So that we may say to our patient with a great deal of confidence that from 15 to 20 years of usefulness may still be his which will bring him up to an age when, if he has read his philosophy aright, he should be able to contemplate transformation with some resignation. During this period, which in many cases is much more protracted, he has not only time to put his house in order but to provide for his dependants. Treatment that can accomplish this can not be passed over lightly, nor is the making of a diagnosis of tabes when this potency is held in reserve quite equivalent to the signing of his death-warrant in the common acceptance of that term.

After all has been said the neurologist's art is but the conspicuous characteristic of every skilful physician, who believes in the curability of disease and who feels that he is but an agent shaping the course through which Nature effects her cures.

32 West 38th Street.

## AN ANALYSIS OF FIFTY-TWO CASES OF TETANUS FOLLOWING VACCINIA.

WITH REFERENCE TO THE SOURCE OF INFECTION.  
1839-1902.\*

ROBERT N. WILLSON, M.D.

PHILADELPHIA.

(Concluded from p. 1152.)

In order to study the question in a judicial manner, and to weigh the evidence for and against an infection carried by the vaccine virus, several points must at once be considered, and in their association and grouping rather than separately. Among these are to be included: 1. The manner of preparation of the virus, the suddenness and proportions of the demand for the same, the care used in testing such virus before being placed upon the market, and finally, the bacteriologic and inoculation experiments that have been possible either before or after infection.

2. The method of vaccination; whether executed in an aseptic fashion, and with such precautions as to prevent unnecessary exposure of the wound during and after the operation.

3. The after-care of the wound, up to and after the time of perfect healing and the dressing employed.

4. The incubation period of the tetanus, always allowing (with a view to thoroughness in our investigation), until there is reason to think otherwise, that the infection has been introduced at the time of vaccination.

5. The clinical symptoms, whether severe or mild; the grouping of the cases as to locality and frequency of occurrence; and the outcome, whether fatal or benign.

6. Any possible and probable source of infection other than the vaccine wound and the vaccine virus.

In considering these questions we must admit in advance that the tendency has been to lay the credit for the tetanus at the door of the vaccine virus, in spite of an overwhelming array of circumstantial evidence that the infection may have been by other agencies. In presenting this mass of evidence for intelligent study, therefore, it has been thought advisable to tabulate the several details under discussion in the accompanying diagram, opposite the number and date of vaccination of each case.

With regard to the first point, the manner and cleanliness of preparation of the virus, it will be necessary to consider three periods in the history of vaccination: that period prior to the knowledge of the infectious nature of tetanus; that subsequent to this discovery, but during which human virus was largely in use; and, that recent period in which bovine virus has been mainly employed.

During the period prior to the knowledge of the infectious nature of the disease (Nicolaier-Rosenbach, 1885-6) reference to our table will show that we have recorded seven cases, two of which (2 and 3) were not certainly, though probably, tetanus. Vaccine material at this time (1839-1885) was largely that obtained from the arm of a human being. As early as 1850 this was at times diluted with glycerin. In all but one of the cases included in this period, as far as could be ascertained at all, the virus used was human lymph. Only one of the seven cases was known to have been vaccinated with "bovine quill" virus. Case 9 followed shortly after and was vaccinated by the "arm to arm" method as before, from a child that was healthy before and after the use of its lymph.

\* Read at a meeting of the Philadelphia County Medical Society, April 23, 1902.

During the second period, or that subsequent to the discovery of the infectious nature of tetanus, but during which human lymph and crusts were still in use, we have in this country records of no cases; but in England (where humanized virus to-day is freely in use) we have Case 9, and a long series of other cases that may or may not have been tetanus, of which a list is appended. All of these were noted in the report of the Royal Commission on Vaccination appointed by the English Parliament in 1889, and many bear the criticism of the Commission that the attending physician was not satisfied as to the nature of the case. (Appendix ix, part i-ii.)

CASE 1.—Female, 6 months old. Arm to arm. Vesicles opened to abstract lymph. None of this used. No other history. Death on seventh day after vaccination from convulsions.

CASE 2.—Male, 8 weeks. Death from convulsions three weeks after vaccination. Virus not known.

CASE 3.—Female, 4 months old. Convulsions on the 18th. and death on the 20th day. No redness or swelling of arm. Arm to arm vaccination.

CASE 5.—Female, age unknown, arm to arm, symptoms of meningitis; greenish scab, poulticed; bronchitis, convulsions 11 days after vaccination, and death.

CASE 6.—Male, age unknown, arm to arm, no surrounding inflammation. Died five days after vaccination. Refused food for two days before death, convulsions.

CASE 7.—E. P., female, age unknown. Child teething at same time. Several convulsions prior to one that caused death.

CASE 8.—T. R., 4 months, female, tube lymph. Eleven days after vaccination death occurred, mouth drawn to one side, unable to make any effort at swallowing, condition of arm satisfactory.

CASE 10.—Vid. Case 9 in above series. Undoubted case of tetanus.

CASE 13.—Child, sex and age not given, tube lymph, from another child. On 8th day slight vomiting and diarrhea. Next day convulsions and death. Vaccination normal.

CASE 23.—Female, 3 months; cellulitis of arm 9 days after vaccination. Lymph from child used. Vesicles became rubbed and red and were poulticed. Swelling on the 14th day. Convulsions and death. A padded shield had been used.

CASE 47.—Female, 4 months, arm to arm. Two months after vaccination convulsions and death. Vesicles had been pricked, and arm inflamed. Large ulcer at site of three vesicles.

CASE 51.—Male, tube lymph from child. Normal vaccination until the 15th day. Bread and milk poultices. Vesicles over the face, hands, extremities, and mucous membranes. Convulsions on the 35th day; death on the 37th day.

CASE 54.—Male, 2 months, arm to arm, vaccination normal to 9th day, then arm red and swollen. Child refused breast. Brawny swelling to shoulder. Convulsions, and death on the 17th day.

CASE 55.—Female, age unknown. Arm to arm. On the second day convulsions lasting 6 days, and then death. Two other children vaccinated at same time did well. Hair-clip needle used, point tarnished "but clean." Ivory spatula used for rubbing on lymph.

CASE 64.—Female, 5 months. Arm to arm. Normal vaccination until 18th day, then neither redness nor swelling. Convulsions on 24th day. Death in 24 hours.

CASE 96.—Male, 12 months, convulsions one month after vaccination, and death.

CASE 99.—Male, 3 months, calf lymph, vesicles pricked on 8th day. On 11th day vaccination normal, bronchopneumonia. Later convulsions and death on the 19th day. Eczema or intertrigo over body for 6 days.

CASE 102.—Male, 3 months, lymph unknown. On 27th day convulsions, and died on following day. Vaccination had healed. No other history.

CASE 109.—Male, 3 months, humanized lymph; erysipelas on 21st day. AgNO<sub>3</sub> applied until raw and sore. On 27th day convulsions and death. Shield used that had been previously in use.

CASE 117.—Male, 3 months. Lymph from child. 8th day erysipelas, inflammation from shoulder to elbow, then to both arms, trunk and extremities. Scabs separated, leaving deep sores. Convulsions, and death on the 26th day.

CASE 127.—Female, 9 months, calf lymph, one other vaccination from same tube normal. During 6th week scabs fell off naturally. Swelling then began at three points. Twelfth week abscess at this point. Nineteenth week abscess in axilla. Twentieth week, and previously, violent convulsions, and death. Tube of lymph had been opened the day before.

CASE 133.—Male, 5 months. Child lymph. During second week vaccination became inflamed, with abscess in axilla. Convulsive attack and death on the 32d day.

CASE 144.—Female, 6 months. Calf lymph. Vesicles pricked on 8th day. Next day child sick, and on 16th day gangrene of the arm. Poultice applied. Convulsions and death on the 20th day.

CASE 158.—Female, 9 months. Calf lymph. Another child, vaccinated with the same tube, normal. Ninth day convulsions and death. Lancet had point broken and was slightly rusted when inspected.

CASE 168.—Female, age unknown. Virus from child. Two children vaccinated from this patient and both did well. On 8th day vesicles pricked, on 9th day redness and swelling, vaccination dressed with fresh cream. Operator "known not to be careful in cleansing his lancet." Erysipelas prevalent. Yard filthy. Convulsions and death.

CASE 174.—Female, 5 months. Calf lymph on points. On 9th day vaccination became red and inflamed from shoulder to elbow. Profuse postvaccinal eruption over buttocks and knees. Convulsions and death on 30th day. Vaccinator used sewing needle, and had attended an erysipelatous patient that day.

CASE 177.—Male, 2 months. Arm to arm, from child who had normal vaccination. On 9th day arm swelled from shoulder to

wrist, became red and angry, then blistered, and became black. On the 12th day, convulsions and death.

CASE 181.—Female, 7 months. Lymph from calf. One other child vaccinated with the same tube had a normal vaccinia. After one month the scars had healed. Eczema of face, scalp and neck. Four months from vaccination convulsion and death.

CASE 183.—Male, 7 months. Arm to arm, and vaccination until scabs knocked off. Began to "take food badly and directly after vaccination." Twenty-four days later convulsions and death. Child had crack over ear; general surroundings filthy, dung-heap beneath window. Two others vaccinated from the same lymph had normal processes.

CASE 187.—Male, 19 years. Arm to arm. Four others vaccinated at the same time and all did well. No dressing on arm. Nine days after vaccination, vomiting, prostration, and double convergent strabismus. On 25th day drowsiness, tenderness of scalp, spasm of right arm. Thirtieth day diplopia, convulsions, death. Diagnosis made of cerebral tumor. No autopsy.

CASE 193.—Male, 5 weeks, calf lymph. On 18th day large ulcer at vaccination site. Offensive discharge. Twenty-third day failed to take its food. Had three convulsions and died a few hours later. Child very dirty and vaselin used on the wound.

CASE 195.—Female, age unknown. Five vaccinated from same arm, and all normal. On the 8th day normal. On the 10th redness over neck and back to the other arm. Parts hard and blisters formed (erysipelas?). Child refused food, had convulsions, and died on the 25th day. Poultice used on the 9th day. Closets and gutters in house unsatisfactory.

CASE 199.—Female, 4 months. Tube lymph from child; vaccination normal until the end of the second week. Then redness, swelling of arm to fingers, and of trunk and extremities. No blisters or sores. Vaccinator known to be unsatisfactory in his methods. Erysipelas prevalent in neighborhood.

Of the above, Cases 8, 22, 117, 177, 183, 187, and 195 were very probably, and all were possibly, examples of tetanus, though they can only be used as evidence of questionable value in this regard. They have, however, an important bearing upon the point next to be considered, i. e., that of the method of vaccination, preparation of the site, and the subsequent care of the wound. Many were admittedly vaccinated in a careless manner, and not one was properly cared for during the course of the vaccinia.

During the third period, or that recent time throughout which in this country bovine virus has been widely used, though in England and on the continent to a lesser extent, we find the great number of our cases; and it is with these that we will have mainly to deal. The fact that human virus, carried directly from one arm to another, has undoubtedly caused a large number of severe ulcers, following which tetanus has developed, will be referred to at a later time, and employed as one of the links in a chain of evidence that grows in length as the study proceeds.

Vaccine virus of former years must then, except for the recent period extending to to-day, be looked upon as mainly of the human variety, and therefore free from any infection other than that already in the system of the child or upon its skin surface. Further than the cleansing of the arm and the lancet (often this was dispensed with) there was no preparation of the virus or the patient, and only one form of virus was used. Only one conclusion is allowed therefore for this period: that the infection came from other sources than the lymph itself, and that abundant opportunity was offered for its transmission. Beginning with the Civil war, or thereabouts, bovine virus came gradually into use in this country, and with its employment the gradual organization of business enterprises to furnish large quantities in convenient forms. Undoubtedly for a long period this production was carried on in a more or less careless manner, especially when large armies were to be vaccinated in a short time. But strange to say, this period records far fewer cases of tetanus in the course of and following vaccinia than the more recent ones in which extreme care is supposedly employed. Our Civil war records, for example, mention not one case of so-called vaccine tetanus. It is not stated, however, and evidently has not been considered, that the cases of tetanus that occurred in the Union Army were in men every one of whom had been vaccinated more or less recently, and that many of

| Case. | Locality.                                     | Date of Vaccination.        | Color, Age, Sex.          | Virus Used.<br>Place on Body. | Dressing Used at Time of<br>Vaccination and Later.                       | Possible Means of Infection Other<br>Than the Vaccine Virus.  |
|-------|---|-----------------------------|---------------------------|-------------------------------|--|---|
| 1     | Plantation near New Orleans.                  | July 31, 1839.              | Adult negress.            | Arm.                          | Presumably none.   | No statement made except as to work in the fields as slave.   |
| 2     | Lowell, Mass.                                 | October, 1845.              | White, 5 years.           | Arm to arm.                   | " "  | Vac. by mother with darning needle.   |
| 3     | Lowell, Mass.                                 | "                           | White, 7 years.           | Arm to arm.                   | " "  | Vaccinated by mother with darning needle; same virus.   |
| 4     | Southern part of U. S. A.                     | May 15, 1879.               | White, male, 3½.          | Arm.                          | " "  | Crust torn away; vaccinated by mid-wife; large ulcer formation.   |
| 5     | Auburn, N. Y.                                 | Jan. 6, 1882.               | White, male, 9.           | "Bovine-quill"; arm.          | " "  | Large ulcer, excavation, lymphangitis, etc.   |
| 6     | Maryland.                                     | Middle of January, 1882.    | White, male, 40.          | Arm.                          | " "  | Extensive ulcer and surrounding inflammation.   |
| 7     | Columbia, S. C.                               | Feb. 9, 1882.               | Colored, male, 5.         | Humanized virus; arm.         | " "  | Small ulcer "bathed in healthy pus" at site of vaccination.   |
| 8     | Havana, Cuba.                                 | May 29, 1886.               | White, male, 2.           | "                             | " "  | Deep ulceration of the tissues.   |
| 9     | England.                                      | Sept. 10, 1889.             | White, female, 2 months.  | Arm to arm.                   | Red rags, ointment, poultice, shield. Bathed with oatmeal water.         | Extensive slough, large ulcer; uncleanly dressing; case of tetanus in neighborhood.                     |
| 10    | Cuba.   | July 12, 1891.              | Negro, male, 9 months.    | "                             | Presumably none.   | Crawling constantly on hands and knees in dirt of yard.   |

them are known to have carried open vaccine ulcers (vid. "Med. History of Civil war") for months, and that probably a certain percentage of the cases was due to infection through the vaccine wound as likely as any other. It is stated, however, (Part III, pp. 634-5), that "The presence of smallpox among the troops raised a demand for vaccine virus, which was supplied in the form of crusts by the medical dispensaries in the northern cities. This stock was wholly from infants, and each crust was accompanied by a certificate bearing the name of the dispensary, that of the child from whom it was procured, and the date of its removal": and again, "A small percentage of the virus used was furnished by Dr. E. Cutter of Massachusetts, who raised crusts from the calf by vaccinating with human virus." On the same page it is noted that "In at least one-half the cases a phlegmon of greater or less size was developed instead of the characteristic vesicle" (Report of Surg. C. Allen). "In many cases a violent erysipelatos inflammation with deep abscesses, destroying the subcutaneous tissues and burrowing under the muscles of the parts affected, producing serious constitutional disturbance" (Report of Surg. W. H. Grimes). And on page 647: "Here we have in the locality some thousands of vaccinations made with the same virus at the same time. In one class a large majority had ulcers; in the other only one experienced any unpleasant effect. It is plain that the men and not the virus furnished the *origo mali*. From other localities the same history came."

The foregoing is not cited at this point to demonstrate either that an infection may or may not be introduced with the virus. Rather to show that during the Civil war large bodies of men were vaccinated with human virus and experienced severe ulcers, and that as a rule no dressing was employed in the care of vaccinated arms. That at the same time in this body, cases of tetanus (505) were noted from various wounds (246, 712 in all) in men who also carried a deep vaccine ulcer; and that very probably some of these cases were similar to those studied in this analysis. Certainly we must arrive at the same conclusion as the reporting surgeon "That the men and not the virus furnished the *origo mali*" as far as the

ulcerative condition was concerned. It is then worthy of consideration that a million and a half of men, all with vaccine ulcers exposed for a greater or less time to conditions so favorable to tetanus infection, could have failed to contract a single case of tetanus through this means of entrance, when 500 and odd cases of the infection (about 2 per thousand) actually did occur from all causes in this body. Certainly, until a recent day the occurrence of tetanus as a complication or sequela of vaccinia has not been recognized by distinguished writers, and even in the most recent text-book (Nothnagel's Encyclopedia, American Edition, 1902) there is no reference to the possibility of its occurrence.

The method of production of the vaccine virus is to-day such a different one from that of 30 years ago, and our methods of observation and publication of our findings so prompt, that we can sometimes arrive at more definite conclusions than our fathers seem to have done. But we are in no way their superiors in the matter of clinical intelligence considering the difference in the facilities at our command, and we have sufficient proof, in the fact that they have never associated the appearance of the tetanus with the introduction of the virus, that they believed the clinical symptoms to indicate otherwise. We now suspect the virus as a natural thing because it is manufactured for profit, and once a salable article can be accused of a flaw there are hundreds ready with the accusation. Nearly the entire output is diluted with glycerin, a small portion only being used in the form of dried points. Recently, just as in the Civil war, an enormous quantity has been called for without sufficient warning to avoid the carelessness of technique that appears inexcusable to-day, but would have been considered scrupulous overcare at the time of the Rebellion. The producers claim that no tube, or point, or dried point leave their laboratories before the lot of virus from which it has been charged has been thoroughly tested upon susceptible animals. Whether this is strictly true in all instances must be left for the individual incredulity to digest. At least in such cases as the recent epidemic of smallpox throughout the United States there has been reason to believe that not only has the virus (non-

glycerinated and glycerinated) been contaminated in a manner that was unwarranted, but that the virus itself was at times so dilute as to render a typical vaccination rather improbable than likely. These are, however, not questions that should detain us long. We know that an attempt, honest or superficial, has been made to supply pure virus to the public at a time when more has been needed than could easily be furnished; but it requires more than the affidavit of an interested party to convince that the virus was pure, in the light of the bad results that have ensued. We have not, therefore, been compelled to rely solely upon bacteriologic and culture experiments, and inoculations, to convince us of the presence or absence of micro-organisms or their toxins. When tetanus began to make its appearance, however, another and more serious question was involved than that of the discomfort and inconvenience, and the conviction required prompt and scientific proof as to where the blame should fall. Up to the present time many experiments have been carried out with a view to discovering the presence of the tetanus spores in the vaccine virus, and especially in the glycerinated form. It has never been seriously considered that the tetano-toxin could be present in the virus, which when introduced into two children, both healthy, from the same capillary tube, seemingly produced tetanus in the one, while the other escaped infection. Only one resort was left: that the tetanus organisms were introduced, or their spores, and remained idle or quiet, for three weeks or more, finally breaking out into an acute and vicious attack of the typical tetano-infection; this, of course, only in the event that the virus was associated at all with the tetanus. In none of the experiments published up to date, however, has success followed the effort to discover the organisms. Many other, and nearly all, of the pus-producing organisms have been obtained and isolated, but the tetanus bacillus never; and so far as this evidence is concerned, it must weigh against their presence. The work in this line has been carried out not only by the writer, but by a number of others whose ability and conscientiousness can not be questioned. The personal experiments of the writer included

anaërobic cultures in all the media and finally a series of tests by the bouillon method recently employed by Levy and Bruns (*Deutsche Med. Woch.*, Feb. 20, 1902), by means of which they obtained tetanus bacilli and their spores in 4 out of 7 specimens of gelatin bought on the market. Bouillon tubes (100 c.c.) were inoculated with specimens of the various makes of vaccine virus (all dated at the same time as the virus used in the Philadelphia and Camden tetanus epidemic), and heated for a time at 75 C., in order to destroy all other bacteria possible without inhibiting the growth of the tetanus germs. The tubes were then kept in the oven at body temperature for 10 days and examined for the tetanus bacilli, and with negative results in every case. Inoculation experiments then remained as the only resort, and were looked upon as conclusive evidence not only of the absence of the micro-organisms, but of their toxin as well, if that were needed. A number of experiments on white rats and guinea-pigs had been carried out by the City Health Board of Camden, N. J., also by the New Jersey State Board, and by numerous individuals (Pitfield, Board of Health of Pennsylvania, *Amer. Med.*, Jan. 25, 1902, et al.) in the city of Philadelphia, all with negative results, not one of the animals developing the disease. My own inoculation experiments upon white mice gave identical results. Of ten white mice injected, two with pure virus as obtained on the market; two with scrapings from a dried ivory vaccine point, and six with specimens from the bouillon culture tubes (into the peritoneal cavity of each 0.5 c.c.), the following results were obtained: In none of the animals did tetanus develop. Of the four vaccinated on the abdomen in the ordinary way, all recovered perfectly from a local inflammation, non-characteristic in type. Of the last six (injected into the abdominal cavity) two died after three days with lesions of peritonitis, and four recovered from an evident indisposition. These results were looked upon as conclusive, but an unusual opportunity was forced by necessity upon the writer and two colleagues of inoculation tests upon the human being. It had appeared that out of some hundreds of thousands of vaccinations performed in Philadelphia and Camden 17 had

developed tetanus within four months' time. Of these some had been vaccinated with the virus of one prominent producer, some with that of another; some with glycerinated lymph, some with glycerinated points, and a number with dry virus on ivory points. The virus of one producer seemed to have been associated with the greater number of cases of tetanus. The results of the tests of these makes have already been mentioned, in one case a portion of one of the tubes that had actually been used being cultured, with negative results. At the same time a regulation was put in force by the City of Philadelphia requiring the successful vaccination of all students of the University of Pennsylvania in whom this was possible, or in whom such successful vaccination had not been obtained within five years. There was no choice but to employ one or all of the "suspected" forms of virus, and as there was little fear of the result in the minds of those responsible, that production was used almost exclusively, which had seemed most unfortunate in the series of Camden cases. The only exceptions were those in which the students bought and supplied their own special choice of virus, this privilege, of course, having been freely extended. All of the students who took advantage of this opportunity, that came under the personal care of the writer, chose for themselves the dry points made by another firm whose dry points had also been used in two of the Camden tetanus cases. The virus used by Drs. Swan, Robrecht, and the writer, who together carried on the work, was obtained at the time when the tetanus epidemic was still in evidence, so that it must have been produced at the same time, approximately if not exactly, with that used in the Camden epidemic. Many of the tubes of lymph bore the same date as those known to have been used in the Camden cases of tetanus. Of the 3000 and odd students all were vaccinated except those that filled the above requirements, and all unsuccessful vaccines were revaccinated at least once, and in several instances as many as eight times. As nearly as could be calculated about 1600 vaccinations were performed. Nearly the same methods of vaccination were employed by the three operators, including a careful sterilization of the skin surface of the arm and the application of a sterile dressing completely excluding the wound from the atmosphere, and renewed at least once daily. The results were the same throughout the student body. Not one case of tetanus developed, although Philadelphia produced in all seven or more cases, all of which are included in the series considered in this paper. In only rarely exceptional instances was there a severe sore at the site of the vaccination. The writer also vaccinated himself with the same virus, and experienced a severe ulcer that healed only after 9 weeks of the most painstaking care. The severity of the process was ascribed either to some infection at the time of the operation or to an unusual susceptibility caused by a lapse between vaccinations of over thirteen years. Reference will be made in the summary at the conclusion of the paper to this series of human inoculations, note simply being made here as to the synchronicity between the latter, those performed upon the lower and susceptible animals, and the cases of tetanus following vaccinia; also to the practical, if not absolute, identity of the virus used in all three instances.

One of the most difficult questions to answer offhand would appear to be that regarding the occurrence of two or more cases of tetanus in the practice of one physician. In the above series Cases 23 and 26 were vaccinated by

the same physician, also Cases 24 and 31 by one man, and finally Cases 27 and 30 by still another. The disease appeared in groups, however, also with regard to time and to place, and far more with respect to the locality. In all these instances many others had been safely and successfully vaccinated by the same men. In a number of instances the same tube of lymph was divided between two children, one of whom died of tetanus, and the other thrived. No one can doubt in such an instance that in one case there was a secondary infection of the vaccine wound by tetanus germs not in the vaccine virus; while in the other only a vaccine ulcer was present that failed to be infected. Such evidence as the foregoing is unusual both as to amount and quality, and is unobtainable in cases that date back even for a few years. In England no such tests were made, and evidently no suspicion was entertained that the virus might have caused the infection. It is interesting in this connection to note that in no case recorded in the literature have tetanus bacilli or their spores been obtained from the vaccine wound, either on the cover-glass preparation or in the culture tube, though many attempts have been made. With regard to the method of vaccination we are also intimately concerned. It is as well known that former methods were dangerous and liable to introduce infection as the fact that to-day most vaccinators realize the responsibility of their task, and take proportionate care in the preparation of the site, and throughout the entire process of vaccination. The larger the surface scarified the greater the surface exposed to possible secondary infection. But apart from a seeming lack of thoughtfulness upon this point we may say that to-day only rarely does a case suffer from the carelessness of the operator. There seems to be no question that Case 41 is an example of just such carelessness, not only in the operative procedure itself, but in the lack of care in the matter of instructing the patient as to the dressing of the wound. Such cases are as rare as they are criminal, and the absence of such a coincident influence in any of the other recent cases reported in this city or in Camden, or in fact throughout the country, is one that is a subject for congratulation. The fact that tetanus appeared after and during vaccinia in the days when vaccination methods were careless, and there was no subsequent care of the wound; and at a time when the healthy virus was carried directly from one arm to another, rather indicates that the same causes operate now as did then, and that if the infection occurs at all it is during or after the operation. Remove the possibility of uncleanly surgical procedure, and there is but one alternative remaining.

The subsequent care of the wound presents a field for thought that comes much closer to the question of tetanus infection than any yet touched upon. In every instance, in the series of cases included in this paper, in which any information could be obtained whatsoever, there has been found (*vid. case histories*) some gross breach in the care of the wound; and usually the presence of some active influence that would offer more than a likely means of entrance for the tetanus or any other infection. Probably no extensive series of vaccinations has been executed with such studied aseptic care, and with such similar methods as that already cited, in the case of the students of the University of Pennsylvania; and probably no such favorable results have ever been obtained from vaccination. The successfulness and effectiveness of these vaccinations were evidenced by the fact that out of the entire student body only one con-

tracted smallpox, and he the son of a homeopathic physician who was at that time and for weeks previous, in attendance upon a case of virulent, confluent smallpox. He had refused to allow his son to be vaccinated until required to do so by the University authorities, and the operation was done so late that it fell far within the ordinary incubation period of smallpox. Of the cases studied in this paper, many wore no dressing upon the arm until tetanus appeared. In fact, until a recent time no dressing was considered necessary; and to-day many men refuse to look upon the surface which they scarify as a surgical wound. Nearly every case showed for days a large open ulcer, burrowing deep into the tissue. Two cases were those of soldiers, sleeping anywhere and everywhere, and looking on a bath as a luxury. Several lived over, and next to, and played continually in stables, the hotbed of the tetanus bacillus. One slept in bed every night with her father who had charge of the horses. Two, at least, are known to have forcibly maltreated the vaccine wound. Many removed the scab for inspection. Two threw or dropped the scab on the ground and replaced it in the wound, one wearing it for hours. One threw his bandage upon the ground and replaced it on the arm at a later time. Several wore a shield over the wound without cleansing or removing until it was full of pus and dirt, and foul to the smell: one of these reached the 18th day, and the writer's case the 28th day with the shield still in place. One, when tetanus developed, exhibited a merino shirt sleeve that had never been washed, matted in the vaccine wound. Two Glasgow physicians in recently reporting a case (*Lancet*, March 22, 1902) sarcastically comment upon the conclusions of the Camden Health Board, and yet they themselves in searching for a "subsequent infection of the vaccine wound" (which they declare impossible) forget that they placed over and around it a "bunion plaster" covered with adhesive strips, and that this was not removed for two weeks. One need not even accuse the skin of furnishing the tetanus infection under such circumstances. For fairness' sake, if they did their duty by the skin, as we are convinced they did, it should be considered as less likely than the "bunion plaster" to have been to blame. One child had been throwing dirt at another shortly before tetanus had appeared. A very few cases had ulcerative lesions on the lips or mouth, or on other portions of the body. Not one had even an approximately aseptic treatment throughout more than a small portion of the time from vaccination to tetanus. Only one was excluded from the chance of outside infection at any time in the course of the vaccinia, and this time was probably so short that it can hardly be considered. And with this point we conclude our investigation of the possibility of outside infection. Because tetanus has occurred in surgical conditions and in operations in which the technique has seemed flawless, no care is too great if the disease is to be prevented. The writer well remembers a series of deaths from puerperal tetanus that occurred in the hospital service of one of his professors during his graduating year and was caused by a bichlorid vaginal douche that carried the tetanus spores. Bauer (Ziemssen's "Cyclopedia") cites many cases of tetanus in which there was no injury to the surface of the body. Tetanus has been known to follow the extraction of a tooth, the application of cupping glasses, the sting of a bee, the catching of a fishbone in the throat, the application of a blister, the hypodermic use of drugs, and during the last year there has been reported a case in which the only abnormality in the body was the presence

of ascarides in the intestine. In the *Medical Times and Gazette*, 1854, p. 376, etc., a long series of cases is cited of tetanus following burns. It seems hardly likely that anyone will consider it probable that the scorching substance introduced the tetanus bacillus or its toxin. Such occurrences indicate that the micro-organisms are always at hand, and that, as with Shiga's and Flexner's bacillus of dysentery in uremia and chronic diseases, the opportunity is all that is needed to start the attack. The bacillus is always to be found in the dirt of the street as has been shown by repeated experiments. Moreover, its distribution varies in localities in such a way as to warrant the statement by Bauer that, "According to the report of Holland the disease is rare in Iceland, while upon the neighboring Island of Heimaey the population would die out if it were not recruited by immigration, since almost all the children die of tetanus." Long Island is an especially afflicted portion of our own country. In the garden soil, the manure, the tetanus bacillus is particularly at home, and there is no doubt that the skin every day, and perhaps always, is the habitat and resting-place of not only some of that dirt, but the tetanus bacillus. Chantemesse and Vidal have obtained pure cultures from the vagina. It does not seem probable that the infection, even in most cases, must come from the skin as suggested by the Drs. Findlay; nor that the proximity of the vaccine wound to the ground had more than a passing influence. They themselves suggest shortly after that the wound was completely sealed from the atmosphere, and in this way they deny their own proposition. In only two of the cases in our series was the vaccination known to be on the leg (Cases 20 and 23), and one of these being a baby was hardly likely to sweep the dirt from the ground "with its skirts." In Cases 24 and 28 the infection almost certainly did not come from the skin, but directly from the ground to the wound. Such opportunities for infection of the vaccine wound as have been cited in the above series would not be considered doubtful in the case of a typical surgical wound. Not even a shield can be looked upon as protection for the vaccine wound. A surgeon would be drummed out of the profession who allowed such opportunities for infection to occur, and by his patients if not by his colleagues. Neither should we hesitate here in fixing upon the probable means of entrance of the tetanus bacillus. Closely allied in its weight of evidence is the period of incubation. Of 50 cases, in which the period of time between the vaccination and the appearance of tetanus was known, in 44 fourteen days or more elapsed, in 31 twenty days or over, in 6 twenty-five or over, in 1 twenty-eight days, in 1 six weeks, and in 1 eight months. In only 5 cases was there any resemblance to the period of incubation ordinarily ascribed to acute tetanus. Two cases (2 and 3) appeared and terminated in a few hours. These cases were vaccinated by the arm-to-arm method and by a darning needle. Graetzner ("Der Krampf, insbes. der Wundstarrkrampf," 1828) has noted a patient whose leg was amputated, and who developed typical tetanus the moment the crural nerve was included in a ligature, and died of tetanus in six hours. Robison (quoted by Bauer) records a case of a negro who wounded his finger with a piece of porcelain and developed tetanus one-half hour later. Ward of Manchester, a case developing tetanus 10 weeks after injury; Friedreich, one three months after injury, and Morgan one two months after the wound had healed. In the latter case the autopsy showed a splinter of wood in the cicatrix (all

*loc. cit.* Bauer). It has already been shown in a previous article that the incubation period in tetanus may vary from a few minutes to many weeks. That of the large number of cases in the Civil war averaged eight days. But there is no variance in the opinions of writers on the subject that the usual incubation period of tetanus, and invariably that of the fulminant or acute type, is comparatively short, averaging about ten days and often amounting to a few hours. In the series now considered there has been an almost invariable occurrence about the 20th day following the vaccination. It has been previously pointed out that this is the time when most often the vaccine wound is exposed through loss or injury of the scab; and also the time when the patient is most likely to be careless of the healing wound. Still more cogent is the fact that it is at just this time that tetanus would be expected if it occurred as a secondary infection of the vaccine wound at the acme of the vaccinia. It must not be forgotten that the tetanus organism may rarely be introduced in substances such as the splinter in the case cited above, and at length be liberated. This, however, can not have been the order of things in the cases under discussion, since no foreign body is introduced in the operation of vaccination that would harbor the tetanus organism other than the glycerin, which is itself a powerful hypodermic irritant, and would tend to accelerate rather than to retard the action of the tetanus process. Two interesting cases have been reported of tetanus infection through a chronic ulcer of the leg, approaching the picture in vaccinia better than any other example offered. The one is noted by Greenwood (*Lancet*, April 30, 1898), and the other by Garnier (*Presse Medicale*, No. 75, 1898), neither ulcer having been cared for, and one being on the leg of a tramp who, presumably, often slept upon the ground. The second was a varicose ulcer. In neither of these cases was any other lesion discoverable upon the body. Such cases are not needed, however, to witness self-evident facts.

The clinical symptoms in 51 out of the entire number of cases when ascertainable have been found to be of the most severe type. In all except Cases 1 and 2 there was well-marked trismus, and if we are correct in thinking that those cases actually were of tetanus, this symptom may have been present. The report is too meager to be of much value. In some cases there were repeated convulsions; in 25 opisthotonos. In all, when the symptom was mentioned at all, there was rigidity of the abdomen, and in many of the whole body. In 11 the course of the tetanus lasted only a few hours; in 24 for under five days; in only 9 for over a week; and the latter cases ultimately recovered after a mild attack. The termination was a fatal one in 41 cases, and recovery followed in 11, giving a mortality of 78.8 per cent., as against 50-60 per cent. as an average mortality in tetanus under all forms of treatment. In the chronic type such as must have been present if the vaccination caused the infection, the prognosis is always fairly good, a large number of, if not most, cases recovering. This feature has been commented upon at such length in a former article that it seems unnecessary to dwell further upon it. If then, we add to the acuteness and severity of the course the general fatality of the series, there seems to be still less ground for doubting the presence of a secondary acute infection. The mortality of tetanus in the Civil war was 89.3 per cent. There remains for discussion only a few minor considerations such as the age, the sex, the time of year, the grouping of cases, the

frequency of occurrence, and the final outcome of the case. Forty-one cases occurred in childhood, and 11 in adult life. Of these 4 were under 5 years, 24 between 5 and 10 years, 12 between 10 and 20 years, and 8 above 20. The large majority of cases of ordinary traumatic tetanus occur in boys or men, and for obvious reasons of exposure, etc. In this series there seems to be little difference between the two sexes (male 28, female 22, sex not stated in 2) in this regard, and perhaps for the equally obvious reason that at the age (childhood) when vaccination is most often performed, both sexes are equally exposed to moderate violence and to contamination from soiled clothing, and uncleanness of person.

It is noteworthy that in the entire series of cases more than half (and all cases of the recent epidemic) occurred between October 1 and March 30. This is contrary to the old belief which gave the summer the greater number of cases. Solly and Simon (*Med. Times and Gaz.*, June 17, 1854) have noted this same autumnal or winter occurrence in a long series of cases. No rule can hold, however, when a requisite condition is the furnishing of a number of external wounds for the entrance of the infection. July 4 in America will cause more cases in the summer than smallpox in the winter, and we must look upon the occurrence of the tetanus simply as being synchronous with the cause that prepares the way. Bauer states, however, that "in one and the same place there are variations in the frequency of tetanus at different times"; that "statistics with regard to certain districts in Europe also show differences in the frequency with which tetanus occurs in these various places."

There has been no well-marked groupings of cases following vaccination previous to the Camden epidemic. Glycerinated points and tubes, dry points, arm-to-arm vaccination, all methods are represented in the above list of cases, and the first three were used in the Philadelphia-Camden outbreak. It has already been mentioned that many of the cases were vaccinated with the virus from one producer. It seems unnecessary to conclude that this was more than a coincidence due to the fact that one production of virus was almost generally in use throughout the eastern portion of the country, and that in this way a far larger number of cases of vaccination were present for infection by the tetanus or any other organism than was the case with any other virus. Wells of Chicago has shown (*Phila. Med. Journal*, June 16, 1900; and *N. Y. Med. News*, June 1, 1901) that the firearms, the cartridges, and the wadding of the same, are not the origin of the July 4 tetanus infection, except as they carry into the firearm wounds means of infection already on the person, and this by a most elaborate and convincing series of experiments. His conclusions are that in all cases the infection has probably been from the skin, and that the wound merely opened the surface to the organism. He also states that in Cook County, Ill., between June 25 and July 14, 1900, there were 27 deaths from tetanus. During the same period in 1899 there were 17 deaths, all in boys (the series upon which his bacteriologic experiments were carried out). Two hundred blank cartridges were examined, representing all the makes used, and in none were the bacilli, their spores, or toxins found. Six samples of street dirt from different places in Chicago all gave cultures of virulent tetanus bacilli. Similar experiments were carried out by Taylor (*N. Y. Med. Journal*, July 20, 1901). He arrived at the same conclusions. Certain parts of Long Island, Chicago, and (judging from the records of the Health Board of our

own city) Philadelphia as well, have annually a long list of tetanus cases. During the year 1901 there occurred in Philadelphia alone 29 cases of tetanus from causes other than vaccination, and during the period Oct. 1, 1901, to Jan. 1, 1902 (the time including the tetanus epidemic), there were in all 12 cases independent of vaccination. In short, there are more cases of tetanus in Philadelphia from other causes during the same period, than from nearly a million open wounds due to the operation of vaccination. During 1899 there were 73 deaths in New York City, and in 1901 there were 32 deaths in Baltimore, all independent of vaccination. Twelve of the latter number occurred at one time. Six occurred in August, 6 in September, and 8 in October (the identical months of the Camden outbreak). Twenty-five of the 32 cases occurred in children under 21 days old, and all were in charge of midwives, none developing in physicians' hands. Twelve cases occurred within a few blocks of one another and under the care of one midwife. Traumatic cases were reported in Camden, Pittsburg, Trenton, and in fact, all of the cities neighboring upon Philadelphia at the same time with those associated with vaccination. No case of tetanus has ever followed vaccination in the District of Columbia, though there have been occasional cases due to trauma. On the other hand, Craig mentions several cases following vaccinia in Brooklyn (1896-1901), though the records can not be obtained. Seven cases have been reported in the newspapers as occurring in Cleveland during 1901 with regard to which no information can be elicited. One case was noted in St. John, Neb. The result of treatment in the cases analyzed in this paper only bears out the evidence already collected. In some cases death was the outcome, although the incubation must have been one of three weeks to have connected the infection with the virus, an unheard-of combination of an invariably long incubation with an acute course and a fatal result.

#### CONCLUSIONS.

Infection has taken place in most if not all cases at the site of the vaccination. We have found that the exact time of infection and the exact means are impossible of absolute and scientific proof: and that the grouping of a large number of cases in a certain locality, and following the use of a certain production of vaccine virus, would tend at first sight to speak for a primary infection, carried in with or by means of the vaccine virus into the system.

On the other hand, we find that a secondary infection, and one occurring as a rule about the time of the acme of the vaccinia, is indicated by the otherwise discordant chronic incubation period and acute symptoms, by the almost uniformly fatal termination, by the severity of the course of the disease, by the millions of normal vaccinations with the same virus, by the simultaneous deaths from tetanus known to be due to other causes, by the diminution in the number of such cases now that continued aseptic care is more generally exercised, by the fact that in every case in which particulars are known over-abundant opportunity was offered for such secondary infection, and finally and most important, by the absolute failure of all bacteriologic and inoculation experiments on the lower animals and man to indicate the presence of the tetanus micro-organisms or their toxin in the virus.

There is neither time nor space to admit of a discussion of the nature of the tetanus itself, or its treatment except to note the fact that out of 13 cases treated with

antitoxin 10 died and 3 recovered (mortality 76.9 per cent.). In all of these cases the usual treatment was employed in conjunction with the serum. Seven cases recovered under the customary routine of chloral, bromids, opium, cocain, and more rarely physostigma; and 32 died (mortality without antitoxin 82 per cent.). Of the entire number of cases 11 recovered and 41 died (mortality 78.8 per cent.). It would certainly seem as if the glycerinated virus, as well as the vicious influence of the shield, was disposed to present a more extensive ulcerative surface and a greater tendency to sloughing than the dried virus, or the arm-to-arm method. The latter is to-day an impossibility on account of the ever-spreading syphilization of the masses. But if it eventually proves true that, as time goes on, glycerinated virus opens a better avenue to the tetanus germ than the less cleanly but safer dried point, we will have to beat a retreat until we discover a substitute for the glycerin that does not carry its disadvantages. Our whole series of cases seems to prove that the infection is one that depends somewhat upon the susceptibility of the person. Otherwise, it must needs be a much more frequent disease. Also that the tetanus micro-organism or its spores must frequently be present upon the skin, and ready to take advantage of an opportunity of entrance. How much more likely this must be the case when the patient is uncleanly, or lives or plays in the street, garden, or stable, needs hardly a word to direct the attention.

A paper such as this would have failed of its mission if it omitted in closing to repeat the statement that the vaccine wound is a surgical condition that requires as skilful care as an abdominal incision. And that the responsibility rests no more with the physician than with the patient to carry out strict asepsis in the care of the same until the perfect continuity of the surface is restored. Otherwise, let the one who relaxes suffer the blame if tetanus develops; and be it doctor or patient that lets down the bars, his carelessness may cost a life and will almost as certainly as the disease develops. The symptoms of tetanus are the sealing of the death warrant, not the beginning of the infection. Fatality may rarely be averted, but the odds are too great to allow the risk. Tetanus in the course of or following vaccinia appears to be no more inevitable or necessary than hemorrhage after the tying of an artery. And if proper precautions be taken, only such cases as are predestined to bleed or to contract in a tetanic spasm will confront the physician. That vaccine virus could be infected with tetanus no one will deny. But that it has been, and in such cases as here come to view, deserves the full denial that has been given by the clinical symptoms and by a careful scientific study. It would appear that tetanus in the course of vaccinia is sometimes an unavoidable accident, due to the indiscretion or wilfulness of children, old or young; but with the principle laid down that the wound shall be treated aseptically from start to finish tetanus will disappear from the pages of the medical books as a complication of vaccination. And had the facts been realized sooner, the condition would never have found a place there.

The writer would acknowledge most cordially the assistance rendered by many physicians in the attempt to secure full clinical details of the cases included in this paper, and especially by Drs. Alfred Stengel, H. G. Wells, F. J. Runyon, and C. Hampson Jones.

*Subscription price: Five dollars per annum in advance*

SATURDAY, MAY 10, 1902.

## TO THE MEDICAL PROFESSION OF THE UNITED STATES:

The necessity for a thorough organization of the medical profession was never more urgent than at the present moment, nor has the appreciation of this necessity ever been more keenly felt than at this time.

The American Medical Association, which will hold its fifty-third annual session at Saratoga on June 10, 1902, being the only national representative association of the medical profession in the United States, is entitled to and claims the earnest support of every medical practitioner who has at heart the highest and best interests of the profession. An organized profession represented in this great central body with affiliated and influential state and territorial associations extending through their subdivisions into all the districts or counties, is the only real guarantee of the protection of the public health and of the medical profession. The enactment and enforcement of rigid medical laws; the establishment of reciprocity or interstate comity by which a uniform standard of requirements for the practice of medicine in the various states, which without any sacrifice of the very highest requirements, would permit a physician, having gone before a competent board in one state, to practice in another without being subjected to a second examination; the establishment of a National Department of Public Health; the support of the medical staff of the United States Army in their effort to maintain their rights; to prevent unjust restrictions upon animal experimentation which has proved to be one of the most important methods of research and of the most lasting benefit to humanity, can be accomplished in no other way than by thorough organization of the profession in the American Medical Association.

JOHN A. WYETH, M.D., President.

## THE NEXT SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

Considerable space is taken up this week with matters connected with the next meeting of the Association. That part which refers to Saratoga shows that village to be an ideal spot for such a large gathering as the coming session promises to be. The hotel accommodation is more than ample and all who attend can be cared for without crowding or inconvenience. The places in which to hold the section meetings will be found satisfactory. Above all, the hotels and meeting-places are

all near to one another, and three minutes' walk will reach the extreme points.

The programs speak for themselves. They show that, from a scientific point of view at least, the Saratoga meeting will be a decided success. They indicate that the best men in the profession of this country will be heard, as well as some from abroad. The ophthalmologic section is to be congratulated on having secured Professor Haab of Zurich to read a paper before that section.

The coming meeting will be the first under the reorganization. The House of Delegates will relieve the general meetings of the legislative functions, and, as these general meetings—except the first and last—will be held in the evening, they will not interfere with the morning meetings of the sections, thus giving more time for scientific work. We look for a marked increase in the value of the papers and discussions and consider that it will be largely owing to this fact. Indeed, the section meetings should decidedly gain in interest from this time on if the increased opportunities are duly utilized and thereby the reputation of the Association as a scientific body will be enhanced. The social features, which are an important side issue in meetings of this kind, will also encroach less upon the regular work without being themselves neglected.

It is worth bearing in mind that this first meeting of the House of Delegates will be an innovation on all previous assemblies of the kind as giving the example of a truly representative body in the medical profession. It is not for this reason in any respect a doubtful experiment; on the other hand, it is only the realization of a long-needed reform, but none the less unique even in this respect. We believe that the coming session, as did the last meeting, in which the reorganization was effected, will take its prominent place among the landmarks of the Association.

## A VOLUNTEER NATIONAL EXAMINING BOARD.

A history of the movement for the regulation of the practice of medicine and for the elevation of the standard of medical education in the United States is an interesting one. First a few and later practically all of the states enacted laws which granted a right to practice to those holding diplomas from any chartered medical college; then this right was limited to those who had graduated from colleges with a specified standard. This standard was usually one of time required to complete the course. At first, two years was sufficient, then three years was necessary, and ere long four years was demanded. Medical colleges have followed by gradually extending their time requirement, so that to-day only two colleges grant the diplomas on less than four years' attendance.

But while the standard has been raised through increasing the time so that it is double what it was a quarter of a century ago, another movement has taken place. Those who were earnestly active in the move-

ment of elevating the scientific and educational standard of the medical profession have always realized that so long as medical colleges were private institutions and conducted on commercial lines they were not to be depended on to decide who were qualified to practice. This has resulted in the enactment of laws in many states creating boards of examiners and requiring all applicants to pass an examination before these boards. At the present time thirty-eight states require examination and nine others require either an examination or a diploma from a recognized college and the number of such colleges in some of these states is very limited. Efforts are being made in those states that do not now require examination to have this substituted for the present plan of licensing on diploma, and we may expect very shortly to find that the ordinary college diploma is not recognized as a sole qualification in any state.

This condition of affairs is very satisfactory from the view point of a better qualified profession, but it has a most unsatisfactory phase—at least to those who desire to remove to another state to practice. Since there are fifty states and territories, including the District of Columbia, a physician desiring the right to practice anywhere in his own country must get fifty licenses. The average young graduate does not know where he will locate; while he is yet well up in all the fundamental branches he would like to go through the ordeal of passing all the examinations so that he can go anywhere he pleases in his own country. But he finds it impossible. Hence he selects his field, conforms to the law of the state and settles down to practice. In a few years he concludes he can do better in some other state, but the ordeal of an examination looms up. He is rusty in most of the fundamentals, and he has made no attempt to keep up in many of the branches: thus to move to another state is to him a serious matter.

A remedy has been suggested in reciprocity, but, as we have stated before in these columns, reciprocity is impracticable. The licensing boards of a few of the states have already grouped together for mutual exchange of courtesies, but reciprocity will never be acceptable to even the majority of the states until there is more uniformity in the laws that now prevails, or is likely to prevail for many years. But even a uniformity of law will not suffice: there must be a uniformity in tests and standards which is impossible under present conditions, wherein the members of most of the examining boards are appointed through political influence and not through the selection of men qualified for the position of examiners in scientific medicine.

In an editorial in *THE JOURNAL* last January<sup>1</sup> we advocated the creation of a national board of examiners as the most satisfactory solution of the difficulty. We recognized at that time that "the constitution of the United States does not place the regulations of the practice of medicine among the functions of the general government, and consequently the practical carrying out of the

idea of a national board is met by obstacles not easily overcome, provided the idea is to compel recognition of certificates from such a board by the various states. The constitutional objections would not apply to such a board as we suggest below. At least the obstacles are no greater here than in carrying out the idea of reciprocity so-called. In either case there must be a voluntary relinquishment of rights on the part of the state, and the state can only give its examining or licensing boards the privilege of accepting the credentials of a corresponding board of another state."

At the recent meeting of the Committee on National Legislation, Dr. W. L. Rodman of Philadelphia brought the subject before the committee and urged the advisability of a volunteer national examining board. The committee, which is representative and national in character, after considering the subject, heartily endorsed the idea and in its report to the House of Delegates will urge that body to take up the subject. We print elsewhere a communication from Dr. Rodman and ask our readers to give it consideration.

If the certificate, diploma, degree or whatever it may be called, of the proposed national examining board is to be accepted by all the states it will be necessary that the board be composed of men of such high standing in the profession and of such scientific attainments, that they will command the respect and confidence of all. The board must be of such a character that to be a member of it will be a high honor; but the remuneration must be sufficient to offset any sacrifice of time the members would have to make to attend to the duties. The fees would without doubt bring in a sufficient sum to meet all expenses, but under no circumstances should the remuneration of the board depend on the fees.

If possible, the creation of the board should be recognized by Congress. As we suggested in our former editorial the board might be created ostensibly to examine applicants for the three arms of the service; at the present time applicants for the medical departments of the Army, Navy and Marine-Hospital Service are examined by boards representing the respective services. While ostensibly the functions of the proposed board would be to pass on the qualifications of those desiring to enter these services, the acknowledged function would be to grant certificates or diplomas which should be a guarantee of a thorough and practical general and medical education. However, it is not absolutely necessary that the board be created by Congress: the degree-conferring bodies of Great Britain, such as the Royal College of Surgeons, the Royal College of Physicians, and the Apothecaries' Hall, of England, and the similar bodies in Scotland and Ireland, while chartered by the government, are private institutions.

The examinations by this board must be rigid, broad, and practical; as suggested by Rodman, the applicants must demonstrate their knowledge in hospitals at the bedside. Above all a thorough general education must be demanded, but not necessarily an academic degree.

The board should meet three or four times a year in as many different parts of the country.

It will, of course, be recognized that such a board would not help those now in practice, as but an extremely small percentage of these would be able to pass such an examination, unless after special preparation for it. It is for the future, for the young men who are ambitious, who want something more than an ordinary M.D., or a state license. The state boards would still exist, as probably only a minor portion of those entering the profession would be qualified, or have the ambition, for the national diploma.

We earnestly commend this idea of a voluntary national examining board to our readers and ask for a free expression of opinion pro and con. The subject will certainly be brought before the House of Delegates at Saratoga in June, and that body will undoubtedly be glad to have the opinion of the profession on the subject.

---

#### MASSAGE AND GYMNASTICS AS THERAPEUTIC MEASURES.

That massage and gymnastics in skilful hands constitute valuable and efficient therapeutic measures of a large range of applicability is no longer questioned by those who have studied the matter conscientiously. In many of the European countries these forms of mechanical therapy are receiving much more attention and encouragement than seems to be the case in America. In Stockholm there has existed for years a fully equipped, legally authorized and regulated institution—"The Central Institute"—for the instruction and training of properly qualified men and women in massage and gymnastics for therapeutic purposes. In order to enter this institute the applicant must possess the degree of bachelor of arts and the course of instruction and training extends over two or more years. In Berlin we understand that these forms of mechano-therapy are represented by a regularly constituted chair in the university.

Graduates from the Central Institute in Stockholm and from other reputable institutes have settled in various parts of the world and successfully practiced their calling, thus becoming in many instances the pioneers in introducing scientific massage and gymnastics. Not a few have found their way to the larger American cities, but up till the present time American physicians have not been sufficiently impressed with the varying degrees of qualification possessed by those who have established themselves as masseurs and gymnasts, and there is no doubt that lack of discrimination may have delayed proper recognition of the value of massage and gymnastics as therapeutic means. It is probable, too, that the general failure of the medical profession to properly interest itself in scientific massage and gymnastics had not a little to do with the development and spread of the peculiar form of quackery known by the anomalous term of osteopathy, which in a large measure simply represents massage run wild and without the proper

control of physicians. The osteopath endeavors by false pretensions to push massage and gymnastics beyond their proper limits, and, although devoid of adequate medical training, he boasts of his skill in treatment of various diseases whose nature he can not understand. He consequently is merely a quacksalver. The educated masseur and gymnast, on the other hand, recognizes that his true position is that of helper of the physician and surgeon without whose advice and recommendation he does not undertake the treatment of patients. No doubt the lack of proper interest in massage and gymnastics on the part of physicians is traceable in large part to the complete absence until recently of any effort to teach students either didactically or practically so much as even the fundamental principles of mechano-therapy.

We have had since the beginning of medical teaching in this country regular courses of lectures on "materia medica and therapeutics," in which there have been marshalled before the bewildered student a vast array of mostly unimportant information concerning the habitat and origin, Latin naming, modes of preparation and doses of medicinal preparations, together with extensive lists of diseases and conditions in which the various preparations, frequently obsolete, have been used with more or less empirical success. Only the other day the candidates for internships in one of the largest general hospitals in the country were asked to give Latin or official names of some 25 substances used in materia medica, among them being such potent and powerful substances as slippery elm bark. It is high time that this sort of teaching is abandoned. Medical students have enough to remember of importance without being compelled to memorize literally the many useless facts of "materia medica and therapeutics" as ordinarily taught. Now the real place for teaching therapy is the clinic, stationary and ambulatory; it is here that massage and gymnastics, for instance, should be introduced to a greater extent than now seems to be the case; and for two reasons, first, because of the real service of massage and gymnastics when properly used in certain suitable cases, and second, in order that medical students, graduate as well as undergraduate, may observe the practical application of mechano-therapeutic measures by properly-trained persons and witness the actual results thus secured.

---

#### THE BALANTIDIUM COLI (STEIN) IN INTESTINAL DISEASES.

The balantidium coli is a normal inhabitant of the large intestine of the hog. It is also occasionally found in the feces of other normal animals, as the dog and cat, but these animals probably become infected by dirt or food previously contaminated by the feces of swine. It is sometimes found in human feces in connection with disease of the intestine, as diarrhea and dysentery, but probably never in the healthy intestine. About thirty instances of infection in man have been reported, mostly from northern Europe, a number from Sweden. Strong

and Musgrave<sup>1</sup> reported a case from Manila. In *THE JOURNAL*<sup>2</sup> reference was made to a case described by Solowjew. The parasite is believed by most writers to be accidentally present and, while finding favorable conditions for growth in the diseased intestine, to probably have no etiologic relation to the diarrhea.

This view is opposed by other observers. Strong, Musgrave and Henschen believe in the pathologic importance of the parasite. In most of the cases which have been examined postmortem, lesions have been found which are very similar to those in amebic dysentery. Solowjew demonstrated the balantidia coli in the walls of the colon from a case showing marked dysenteric lesions. He believed that the balantidia, by virtue of their active, independent movement, might penetrate the mucosa, passing between the glands, and reach the mucosa, giving rise to necrosis and ulceration. Strong and Musgrave also demonstrated the parasites in the intestinal wall, most abundant in the submucosa, and penetrating for a short distance between the muscular layers.

Of interest in this connection is the description by Harlow Brooks<sup>3</sup> of an epidemic of dysentery caused by the balantidium coli, occurring among the apes of the New York Zoölogical Park. Five apes were affected with a severe dysentery. Two of the animals died after a few days and the bodies were examined postmortem. The principal changes were located in the cecum, in the lining of which were extensive ulcerations, irregular in contour and with undermined borders. Microscopic sections through the ulcers showed a destruction of the mucous and submucous coats, the floor of the ulcer being the muscular coat; in others the destructive process extended down to the peritoneum. Extensive undermining of the bordering mucous membrane was one of the chief characteristics of the ulcers. Local inflammatory infiltrations were not frequent. The balantidia coli were found in great numbers in the sections, filling the floor and sides of the ulcerations. From the floor and sides of the ulcers, the infusoria extended outward, being found in the muscular coats, apparently penetrating along the course of lymphatic and blood vessels. The parasites appeared to enter the submucosa from the bases of the crypts of Lieberkühn, in which glands they are often present. While the diarrhea was present, the feces of the apes contained the balantidium coli, but as soon as the animals recovered and the stools became formed the infusoria disappeared. Relapses after apparent recovery were frequent and each relapse was accompanied by the presence of the balantidia in the feces. The location of the infusoria deep in the glands of the intestine may explain the difficulty of reaching and completely destroying them, and so the liability to relapse. Brooks has not succeeded in reproducing the disease experimentally, but he has been unable to employ apes because of their expense. These cases in apes

with so many of the clinical and anatomic characteristics of amebic dysentery, are most interesting. The demonstration of the parasite in the intestinal tissues, extending outward in advance of the destructive changes, furnishes as convincing proof of its etiologic relation to the intestinal lesions as do similar demonstrations in the case of the ameba coli in amebic dysentery. Since Stiles has shown the balantidium coli to be very abundant in the feces of pigs in Iowa, it seems likely that cases of infection by it might be observed there. As this infection will naturally occur in the country, the cases will come under the notice of country practitioners, and it is to them that we must look for their detection. It is not unlikely that the more general examinations of feces which seem about to be carried out will disclose cases of infection with balantidium coli in this country.

Brooks' observations also call attention to the fact that the study of disease in the animals most closely related to man may be of much value in helping to clear up certain obscure problems in human pathology.

#### THE OHIO MEDICAL LAW.

The last issue of *American Medicine* contains an editorial commenting on a recent decision of the Supreme Court of Ohio in which it sees a nullification of the medical practice laws of that state. At the same time it points out that, viewed from this standpoint, it also practically amounts to nihilism in the administrative departments of the government of Ohio. If such is the case, we do not see the necessity of the forebodings of our contemporary. The Supreme Court has, in such case, evidently made a mistake and will utilize its first opportunity to correct it. Court decisions on constitutional questions are not—like the laws of the Medes and Persians—altogether beyond the reach of auto-revision: if the interpretation of the constitution in one case seems to nullify an act of the legislature, it does not necessarily follow that the same result will follow in another. Certainly, the constitution does not commit inevitable suicide by annihilating the executive part of the government. As we read the decision it does not essentially nullify the medical practice act which certainly furnishes standards enough apart from the mere will of the examining boards. Nor can we see how it need necessarily affect the examination provisions of the law. Undoubtedly the quacks and other opponents of medical laws will utilize this decision as much as they are able, but we reserve a serious doubt of their success. It would be a pity if the medical law of Ohio, which has so far worked so well, at least apparently, could be overthrown by the side wind of a decision on an entirely different act. The medical board in that state deserves credit for effectively executing the law, as is shown, for example, in an item in our news columns of last week, in which notice was given of the prospective suspension of one of the medical colleges of the state on account of the rigidity of the preliminary qualifications required. If a medical college—a professional school—can not exist without admitting those who have not even a decent high school education, it ought not to exist. There are, how-

1. Bulletin of Johns Hopkins Hospital, February, 1901, 31.

2. Jour. A. M. A., Aug. 24, 1901, 518.

3. N. Y. Univ. Bulletin of the Med. Sciences, January, 1902, 1.

ever, many such and they exist and flourish because our state laws too often ignore preliminary qualifications or, it may be, because state boards are lax in the enforcement of the requirements.

#### HAVANA'S EXCELLENT SANITARY RESULTS.

The published report of Maj. W. C. Gorgas, chief sanitary officer of the City of Havana, is an interesting document. It includes only the period ending Dec. 30, 1900, but in this some of the most striking results of the introduction of proper sanitation into a district where it had been notably neglected were apparent. Aside from the question of yellow fever, the etiology and prophylaxis of which were practically settled during the period, the results with other diseases are also remarkable. Tuberculosis, which during the decade 1890 to 1899, had a mortality of 1683 annually, or 7.5 to each 1000 of the population, was reduced to 5.39 in 1899 and 3.40 per 1000 in 1900. If there could be any doubt as to the effect of proper sanitation on the prevalence of this disease the progressive reduction here produced ought to settle it, supporting as it does the facts given from other localities. It shows, moreover, that conditions, not contagion, are chiefly responsible for its mortality. The fatality of other disorders due to unsanitary conditions was also reduced, enteritis dropped from 1163 deaths in 1899 to 560 in 1900 and typhoid fever from 240 to 90. Yellow fever, on the other hand, not being affected by general sanitation, increased in 1900, largely on account of the immigration of non-immunes, but the demonstration of its method of infection made that year has since enabled the authorities to furnish one of the most striking examples of the control of a pestilential disease afforded in the history of medicine. If the Spanish war did no other good, this result would have been worth all its cost, and more, to the world. It is to be hoped that the incoming Cuban government will continue with like success the sanitary measures instituted by the military authorities during the American occupation. It is what they are bound to do under the conditions enforced as a matter of self-protection by the United States, and the world generally will watch with interest how they meet the responsibility.

#### THE PARATHYROID GLANDS.

The embryology and physiology of the parathyroid glands have been studied extensively by various observers, but practically nothing is known so far concerning the pathologic changes that may occur in these structures. A beginning is made by Benjamins,<sup>1</sup> however. He finds that in man these glands generally occur in pairs, one on each side, and that they develop probably from the fourth branchial clefts. Kohn and others observed a duct-like passage in connection with the parathyroids: Benjamins regards this duct as analogous to the thyroglossal duct, and he proposes for it the name *ductus parathyroideus*. It would not be surprising were this duct to become the seat of cystic dilatation in cases of incomplete obliteration, thus forming an additional variety of cyst in the neck. Benjamins noted that the usual regressive changes occur in the parathyroid glands

as in other organs; in a case of general miliary tuberculosis tubercles were found throughout the parathyroids. These structures do not seem to undergo any special or specific changes in goiter. So long as we are not adequately informed in regard to the functions of parathyroid in man, surgeons would act wisely by leaving them behind whenever that is possible in thyroidectomy. They are found mostly on the posterior free margins of the lateral lobes of the thyroid near the branches of the inferior thyroid artery. Experienced observers will probably have but little difficulty in recognizing the parathyroid, but at first it is very difficult, if not impossible, to distinguish them from small lymph nodes, more particularly hemolymph nodes, which may occur in this region. Benjamins fully describes a tumor of parathyroid structure developing in a man of 57. It grew slowly until it reached the size of a child's head, was irregularly nodular, and surrounded by a fibrous capsule. Microscopically, it proved to be of papillary structure, the epithelial cells greatly resembling those of the parathyroid with small clumps of colloid here and there between the cells. Undoubtedly other instances of tumor growth in connection with the parathyroid will be described soon now that attention has been directed to this possibility.

#### ABILITY AND THE SIZE OF THE HEAD.

The relation of the size of the head to size of brain and correspondingly to the grade of intellect is generally accepted as a fact by the public and to a large extent by scientific men. It has its basis in the well-known facts of microcephaly, but within the reasonable limits of head size as carried by average rational individuals there have been no absolutely certain data for the solution of the question. Some great men have had small heads and vice versa. Professor Karl Pearson, the English mathematical biologist, has attacked the question in a communication to the Royal Society (abstracted in *Nature*, April 10) in his own special way, utilizing the records and measurements of the honor men at the Cambridge University examinations as compared with the average, and also the figures from schools. He considers in these cases the ability as shown in various ways, the judgment of teachers, the results of examinations and the subject's own estimate of himself, and compares these factors with the data as to size and shape of the head, utilizing strict mathematical methods in the investigation. The ultimate result reached by him is that there is no appreciable or necessary relation between ability and the size and shape of the head—that is, of course, within the average range as heads are met with. This finding will, of course, not be conclusive as regards special cases, for there will always be evidence that, exceptionally at least, large cranial and brain development attend marked ability. The mental make-up, moreover, is so complicated that no absolute criterion of ability can be established, the brain balance may fail in some essential point and a "mute inglorious Milton" the result. Indeed, it seems possible that ability in any line is to a certain extent an accident and it may perhaps be occasionally even pathologic. The equal development of brain and its faculties to a very high grade is almost an impossibility, hence the small, well-

1. Ziegler's Beiträge, 1902, xxxi, 143-182.

balanced organ may show better functional results than the larger but somewhere or other less perfectly adjusted one. There is abundant good reason to accept Professor Pearson's result as stating the rule, to which, however, as with other rules, there may be notable exceptions.

## Medical News.

### CALIFORNIA.

**Fatality in Hospital Fire.**—The north wing of the King's Daughters' Home for Incurables, Oakland, was destroyed by fire, April 28. Despite the heroic efforts of the matron, nurses and attendants, one inmate was fatally burned and another will probably die from injuries received.

**Cooper Medical College Commencement.**—On April 29, Cooper Medical College, San Francisco, graduated a class of 25. Rev. Frederick W. Clappett, D.D., delivered the address to the class, and Dr. Albert H. Taylor, the faculty valedictory. The degrees were conferred by Dr. Charles N. Ellinwood.

**Illegal Practices and Practitioners.**—The jury system seems to work hardships to the efforts of the State Medical Society to punish unlicensed practitioners. In a recent case the jury returned the verdict: "We, the jury in the above-entitled action, hereby agree to disagree."—Sylvester W. Richmond, a "trance-physician" of Los Angeles, was convicted of practicing without a license.—C. J. Schmidt and Genaro P. Yglesias, "worm doctors" of San Diego, who have been in trouble before on account of "knife-plays" and illegal practices, have again been arrested.

**Change in Medical Course.**—The faculty of the University of California has adopted a new pre-medical course, by the terms of which students will no longer be allowed to receive the degrees of M.D. and B.S. upon the completion of six years in the University, three in the academic and three in the medical department, as heretofore. However, on the completion of the new pre-medical course in the College of Natural Sciences and of the first two years in the medical department students may be granted the degree of B.S. on recommendation of the faculty of the College of Natural Sciences. This change is a result of the reorganization and extension of the medical department, which will no longer allow students who have taken the three years' pre-medical course at Berkeley to be admitted to the school.

### COLORADO.

**Emergency Hospital, Denver,** will be reopened in its permanent quarters at Curtis and Fourteenth Streets about May 15.

**Pesthouse Burned.**—An incendiary fire destroyed the isolation hospital of Victor, April 24. The loss was \$1200, with no insurance.

**New Hospitals at Victor.**—The new private hospital of Drs. McKenzie and Welles was formally opened May 3.—The new Teller County Hospital is to be opened to-day.

**Gift to Glockner Sanatorium.**—Otto Young of Chicago has given \$5000 to the Glockner Sanatorium, Colorado Springs, for the purpose of erecting an addition to the institution, conditional on liquidation of the debt on the sanatorium.

**Maternity Hospital Dedicated.**—The Denver Maternity Hospital was dedicated with appropriate ceremonies, April 20. Dr. Horace G. Wetherill, president of the Hospital Association, delivered an address in which he explained the need for the establishment of the hospital. Bishop Warren, Rev. R. F. Coyle and Dean Hart of St. John's Cathedral participated in the dedicatory exercises.

### DISTRICT OF COLUMBIA.

**Howard University Graduates.**—The Medical Department of Howard University, Washington, held its commencement exercises, May 6, graduating a class of 27.

**For an Isolation Hospital.**—The district commissioners have received from the Senate district committee a copy of an amendment to the District appropriation bill, intended to be proposed by Senator Gallinger, providing that the commissioners are empowered and directed to acquire Anacostan Island, in the Potomac river, at a cost not to exceed \$125,000, or by condemnation proceedings conducted in accordance with the terms of the act which provided for the securing of an

eligible site for the new city postoffice building. The island is to be the site of the isolation hospital for the District.

**To Amend Virus and Serum Bill.**—The District Commissioners received, April 21, from the Medical Society, a report by its executive committee inviting attention to a bill pending in Congress to regulate the sale of viruses, serums, toxins and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes (S. 4960 and H. R. 13392). The committee recommends that section 4 of the pending bill, which provides for the promulgation of regulations by the Secretary of the Treasury on the recommendation of the supervising surgeon-general of the Marine-Hospital Service be stricken out and the following inserted in its place:

Section 4. That the surgeon-general of the army, the surgeon-general of the navy, the supervising surgeon-general of the marine-hospital service, the chief of the bureau of animal industry of the Department of Agriculture and the health officer of the District of Columbia be, and they are hereby, constituted a board, with authority, subject to the approval of the Secretary of the Treasury, to promulgate from time to time such rules as may be necessary, in the judgment of said board, to govern the issue, suspension and revocation of licenses for the maintenance of establishments for the propagation of viruses, serums, toxins, anti-toxins and analogous products, applicable to the prevention and cure of diseases of man, intended for sale in the District of Columbia, or to be sent, carried or brought for sale from any state, territory or the District of Columbia into any other state, territory or the District of Columbia, or from the United States into any foreign country, or from any foreign country into the United States: Provided, that all licenses issued for the maintenance of establishments for the propagation and preparation in any foreign country of any virus, serum, toxin, anti-toxin or product aforesaid, for sale, barter or exchange in the United States, shall be issued upon condition that the licensees will permit the inspection of the establishments where said articles are propagated and prepared, in accordance with section 3 of this act.

Section 5. That the Secretary of the Treasury be, and he is hereby, authorized and directed to enforce the provisions of this act, and of such rules and regulations as may be made by authority thereof, to issue, suspend and revoke licenses for the maintenance of establishments aforesaid, and to detail for the discharge of such duties such officers, agents and employees of the Treasury Department as may in his judgment be necessary.

The executive committee recommends that this bill, amended as suggested above, be indorsed by the Medical Society, and that the executive committee be authorized to take whatever action may be necessary to secure its enactment.

### ILLINOIS.

**Reckless Extravagance.**—At a special meeting of the Litchfield City Council, April 15, the members of the Board of Health were granted a salary of \$2 for each meeting, the salary not to exceed \$10 a year.

**Appalling Prevalence of Abortion.**—At the meeting, May 1, of the Livingston County Medical Society resolutions were adopted, that it regarded the crime of feticide as cowardly murder, that it was determined to bring to justice the perpetrators of this crime and that it strongly deprecated all means taken to lessen the birth-rate.

**Personal.**—Dr. J. W. Robinson, Atlanta, has located in Tonica.—Dr. Marcus S. Fletcher, Ridge Farm, has been appointed physician of Vermilion County to succeed Dr. William A. Cochran, Danville.—Dr. I. W. Blake, Rock Falls, has moved to Ladysmith, Wis.—Dr. Samuel A. Graham, Waynesville, has been appointed to the staff of the Illinois Eastern Hospital for the Insane.—Dr. Ralph Hanson, Lewistown, has moved to Spokane, Wash.: Dr. Samuel A. Oren, Lanark, succeeds to his practice.

**Blessing Hospital Staff Named.**—The annual meeting of the staff of Blessing Hospital, Quincy, was held April 30. Dr. Levin H. A. Nickerson was elected president, and Dr. Edmund B. Montgomery, secretary. The following were elected to the staff: Physicians—Dr. Ernst Zimmermann, attending; Drs. Henry Hatch and John H. Rice, consulting; surgeons—Dr. Robert J. Christie, Jr., attending; Drs. Edmund B. Montgomery and William W. Williams, consulting; gynecologists—Dr. Sarah Vasey, attending; Dr. William S. Knappheide, consulting; obstetricians—Dr. Melinda C. K. Germann, attending; oculists and aurists—Dr. Frederic M. Pendleton, attending; Dr. Frank E. Tull, consulting; anesthetizer—Dr. Clarence A. Wells; advisory board—Drs. Levin H. A. Nickerson, Edmund B. Montgomery and John H. Rice.

### Chicago.

**New Building for Dunning.**—The county board decided, May 3, to erect a building for general purposes at Dunning, to cost \$20,000. The building will accommodate 100 patients.

**Osteopath Fined.**—A Chicago osteopath named Young, was fined \$25 at Valparaiso, Ind., May 1, for violation of the state

law requiring a license to practice medicine. An appeal to the Circuit Court was taken.

**Hospital for Aged Jews' Home.**—Mrs. Morris Rosenbaum has donated \$25,000 to the Home for Aged Jews, to be spent in the erection of a fireproof 40x60 hospital, which will be outfitted by the daughter of Mrs. Rosenbaum.

**Dowieite Elder Seeks Vaccine.**—The object lesson of smallpox in "Zion" has apparently had a salutary effect on the *ci-derant* anti-vaccinationists of the Dowie cult. On April 29 Dr. Speicher called on the Health Department for protection from a case of smallpox on the South Side, near a colony of Dowieites.

**Colonel Wilcox Transferred.**—Lieutenant-Colonel Timothy E. Wilcox, chief surgeon, Department of the Lakes, Chicago, has been ordered to Vancouver Barracks, Washington, for duty as chief surgeon, Department of the Columbia. He will be succeeded by Lieutenant-Colonel C. L. Heltzman, who is now on his way home from the Philippines.

**Public Health Good.**—Aside from scarlet fever the public health conditions are fairly satisfactory and a continuous decrease of mortality during the next two months is anticipated. The highest number of deaths, 19, from scarlet fever during the present epidemic was reported last week. With inadequate hospital facilities and the carelessness of too many parents, and even of physicians, in the matter of isolation and disinfection there is little prospect of the epidemic subsiding until the material is exhausted.

**Death Rate Lowered.**—For the second time this year the Department of Health reports the total deaths recorded as fewer last week than for corresponding weeks of last year and for the first time since May 15, 1897—nearly five years—no death was reported from typhoid fever. The total deaths last week numbered 504—an annual death rate per 1000 of 14.44—being 46 fewer than the week previous and 62 fewer than a year ago. These figures represent a decrease in the death rate per 1000 of 8.2 and 13.8 per cent. respectively.

**The Recommendation Supply Waning.**—During the past week only four recommendations have been added to those heretofore chronicled as emanating from the officers-of-the-day at the County Hospital. These are: 1. That a bulletin board be established for announcing unusual and interesting cases treated by internes, that other internes might discuss the cases and criticize the treatment. 2. That a wardrobe be established to provide clothing for needy persons dismissed from the hospital. 3. That the city establish an especially-constructed hospital for contagious diseases, which could be so operated as to pay expenses. 4. That Recommendation 3 be carried out.

**Nurses' Convention.**—The fifth annual convention of the Nurses' Associated Alumnae of the United States adjourned, May 3, after electing Miss Mary Riddle, Boston, president; Misses Harriet Fulmer, Chicago, and Sarah Rudden, Philadelphia, vice-presidents, and re-electing Miss Tamar Healy, Brooklyn, treasurer, and Miss Mary E. Thornton, New York, secretary. One of the most important matters considered was the securing of legislation providing for the registration of nurses and their recognition by the state. Already two states are organized for such effort with the legislatures—New York and Illinois—and the result of the report and discussion at this meeting will probably be similar organization in other states. This will mean in time the establishment of a universal curriculum and an extension of the course of study from two years to four in all training schools.

**Spectacle-Fitting Not Practice of Medicine.**—The Appellate Court of the Second District of Illinois, in the case of Smith vs. People, has decided that an itinerant oculist and spectacle-fitter is not engaged in the practice of medicine. The appellant advertised as the "Great Chicago Eye Expert," and his advertisements also contained the following: "If you have blurring, dizziness, neuralgia, headaches, spots before the eyes, inflammation, granulation, winking, trembling spells, cataract, burning and smarting of the eyes, various brain affections entailing not only positive injury to the sight, but untold misery, call immediately." The court reasons that this is not the practice of medicine; "the defendant did not cure any of these ailments, that whenever his patrons ceased using the glasses defendant had supplied to them, their prior troubles returned." The case has been carried to the Supreme Court.

#### INDIANA.

**Union Hospital Staff Feasts.**—The annual banquet of the staff of the Union Hospital, Terre Haute, was given, April 24. Dr. Stephen J. Young officiated as toastmaster.

**Greene County Medical Board** was reorganized at Switz City, April 17, with Dr. Elmer Shirts, Lyons, president; Dr. James E. Tallbot, Linton, vice-president, and Dr. C. B. Mallott, Linton, secretary.

**The Physicians' Defense Company** has filed articles of incorporation at Fort Wayne, showing a capital stock of \$100,000. Its purpose is to aid and protect members of the medical profession from prosecutions in civil malpractice suits. The company will contract to defend physicians for a certain consideration for a certain period.

**Medical College of Indiana Commencement.**—The thirty-second annual commencement exercises of this institution were held at Indianapolis, April 24. The address of the evening was delivered by Rev. George Harris, LL.D., president of Amherst College, who spoke on "Ideals and Progress." Hon. Addison C. Harris, president of the University of Indianapolis, then conferred degrees on a class of 75.

**Ober a Fugitive.**—Dr. George McD. Ober, who conducted a so-called medical institute in Indianapolis until last winter, when he was arrested, charged with practicing medicine with a fraudulent license, and who afterward went to Madison, where, at the instigation of the Jefferson County Medical Society, he was again arrested on a similar charge and released on bonds, failed to appear for trial. Judge Bear of the Circuit Court thereupon spoke of the numerous complaints of the citizens in various parts of the county of the manner in which the defendant had served them, they claiming that Ober would agree to bring about a cure for \$50 and would take their note for the amount negotiable at a bank and leave a bottle of medicine and never be seen by them again and would sell their notes. He said the citizens of the county were entitled to protection from such traveling doctors, that the able physicians of the county, who had paid out large sums of money in fitting themselves up for this important duty, were also entitled to protection, and that no one should be entitled to practice in this territory unless he were legally licensed. He thereupon ordered that Ober's bond be raised to \$500, a new warrant issued for his arrest, and the case continued until the next term of court.

#### IOWA.

**Drake Medical College, Des Moines,** held its commencement, April 21, graduating a class of ten. Chancellor W. B. Craig of the university conferred the diplomas.

**Dr. Middleton's Will.**—The will of the late Dr. William D. Middleton, Davenport, has been filed for probate. It leaves his entire estate to his wife, who is made sole executrix without bond.

**Sioux City College of Medicine** graduated a class of ten at its twelfth annual commencement, April 30. Dr. William Jepson delivered the doctorate address, and Dr. George W. Beggs, president of the board of trustees, presented the diplomas to the class.

**Personal.**—Dr. Harry J. Watson, late of Ottumwa, has been placed in charge of a brigade hospital in the Philippine Islands. He has recently been recommended for promotion for distinguished bravery.—Dr. Allen L. Bryant, Marshalltown, has moved to La Moille.—Dr. Charles L. Stubbs, La Moille, will locate near Walla Walla, Wash.—Dr. John P. Harrel has been appointed health officer and city physician of Burlington.

**Will Build.**—The board of regents of the University of Iowa held its annual meeting at Iowa City, April 5. It was decided to erect a medical building to cost \$200,000 on property given by the citizens to the university several years ago if reasonable prices for land desired could not be obtained. To locate the medical building thus will close up a street that has been kept open by the university.

#### MARYLAND.

##### Baltimore.

**Endowment Fund Increased.**—At the meeting held, May 2, to increase the Johns Hopkins endowment fund, \$60,000 was contributed.

**Fraternity Reunion.**—The annual reunion of Maryland Chapter Alpha, of the Phi Beta Kappa Society, was held at Baltimore, May 2.

**Reunion and Banquet.**—The University of Maryland class and hospital staff of 1892 held a reunion and banquet May 3, Dr. John Turner being toastmaster.

**Banquet.**—The second annual banquet of the Alumni Association of the Baltimore Medical College was held, April 28,

about 200 attending. An address was delivered by Dr. Robert W. Johnson. The alumni gold medal for the best thesis was presented to Dr. Arthur P. Herring.

**The Maryland Woman's Quarter Club** is meeting with success in collecting subscriptions for the building of a sanitarium for consumptives in the mountains of Western Maryland. The subscription books will be gathered in May 14. About \$1400 is now in hand, and 1000 new subscription books have been issued, returnable November 15.

**Health Wardens.**—The health commissioner appointed the following as health wardens: Drs. F. Caruthers, J. A. Schulte, C. M. Schulte, Thomas Sudler, F. A. Sauer, A. C. Hearn, A. S. Gage, J. W. France, H. T. Westbrook, J. F. Hempel, Claude Van Bibber, T. L. Richardson, D. S. Williams, A. G. Barrett, J. L. Ridgely, M. K. Warner, C. F. Flautt, R. A. Warner, M. G. Smith, H. J. Hahn, E. C. Garee, A. T. Chambers, H. Lee Frank, and L. J. Turlington.

**Library of the Medical and Chirurgical Faculty.**—The annual report shows a very prosperous condition of the collection. During the year the additions have been 926, including 100 rare old volumes purchased abroad by Dr. Osler and the Upton Scott collection of 114 volumes presented by Dr. Clotworthy Birnie. There are 144 journals regularly received. There have been 3897 readers during the year, and 2057 books loaned out to 229 members. This now really valuable collection of 14,000 volumes is becoming the constant resort of a large number of the profession, not only of Baltimore, but of Maryland, and the comfortable Frick quarters with the easy chairs and the long oaken tables are a great boon to many. The benefits derived are seen in the improved character of the papers read before the local societies and published in the journals. From statistics it appears that this library is attended and used as much as others of much larger size.

**University of Maryland School of Medicine.**—The graduates of the University of Maryland School of Medicine, 76 in number, have been announced. Dr. A. M. Shipley won the gold medal. The following appointments have been made: Assistant resident physicians—M. L. Price, M. R. Thomas, and B. B. Ranson; assistant resident surgeons—Nathan Winslow, A. M. Shipley, H. L. Rudolph, and S. R. Donahoe; assistant resident gynecologists—M. V. West and J. F. Hanes; assistants at Bayview Asylum—Charles D. Grover and Philip L. Traverse. The meeting of the Alumni Association was held May 2, the address being by State Comptroller Hon. Joshua W. Hering, M.D., class of 1855. Dr. John T. King was elected president for the ensuing year. A badge was adopted and a committee of ten appointed to make arrangements for the centennial of the university, which will occur in 1907. The annual commencement was held May 5, Governor Montague of Virginia being the orator.

#### MASSACHUSETTS.

**Alleged Doctor Fined.**—Edward E. Willard, colored chiropractist, was found guilty of the unlawful practice of medicine at North Adams, April 30, and was fined \$100, or in default will serve four months in jail.

**The Lynn Medical Fraternity** tendered a complimentary dinner, April 30, to Dr. William S. Gottheil of New York City, who addressed the fraternity on "Diseases of the Skin, and Syphilis," illustrated by stereopticon.

**Harvard Medical School.**—Harvard College has now entered into formal possession of the site for its new medical school. The title is taken by the president and fellows of the institution, and the consideration given is \$606,008. The land which comprises the site of the new medical school was conveyed to the trustees representing the college in August, 1900. It is a very large tract, comprising 1,128,824 feet of land.

**Hospital Appointments.**—Franklin County Hospital Medical Board has elected Dr. Augustus C. Walker, president; Dr. Enoch G. Best, vice-president, and Dr. Benjamin P. Croft, secretary and treasurer, all of Greenfield.—Dr. Charles A. Shackford has been re-elected chairman, and Dr. J. E. Blaisdell elected secretary of the medical board of Frost Hospital, Chelsea.—Dr. J. Clark Hubbard has been elected superintendent of the Holyoke City Hospital, vice Dr. Charles O. Carpenter, deceased.

**Changes in Faculty of Tufts Medical College.**—New appointments on the faculty and boards of institution of Tufts College Medical School, Boston, are as follows: Edward O. Otis, M.D., professor of pulmonary diseases and climatology; Francis D. Donoghue, M.D., instructor in clinical surgery; Henry S. Warren, M.D., assistant in orthopedic surgery; J.

Sheppard May, M.D., assistant in clinical medicine and obstetrics; Charles H. Winn, M.D., Arthur W. Fairbanks, M.D., John P. Treanor, M.D., and H. F. R. Watts, M.D., assistants in clinical medicine; James W. Hinkley, M.D., assistant in obstetrics; L. Mary Belle Holt, B.L., assistant in anatomy; Florence Gilman and Frank H. McElroy, assistants in general chemistry; Arthur H. Makechnie and Walter W. Kingsbury, assistants in medical chemistry and toxicology; Freeman A. Tower, assistant in physiology, and John A. Whittle, assistant in histology.

#### MICHIGAN.

**The Honored Dead.**—The board of control of Lansing City hospital has passed resolutions regarding the death of Dr. Charles N. Hayden, Lansing.—The physicians of Berrien County met at Benton Harbor, April 10, to pay tribute to the memory of Dr. John Bell of Benton Harbor.

**Michigan College of Medicine, Detroit,** held its fourteenth annual commencement, April 24, graduating a class of thirteen. Rev. John McCarroll, D. D., delivered the address to the class on "Medicine, Law and Religion." Dr. Lewis E. Maire presented the class to Dr. William I. Hamlen, who administered the Hippocratic oath and presented the diplomas; Dr. John F. Bennett delivered the doctorate address, and Dr. Abram Goodfellow the valedictory.

#### NEW YORK.

**The Stony Wold Association,** which has for its object the establishment of a sanitarium in the Adirondacks for the treatment of as many as possible of the 20,000 tuberculosis sufferers in the tenement districts, in its first year has raised more than \$50,000 for the furtherance of this object.

**New State Hospital Needed.**—Owing to the overcrowded condition of the State hospitals and the yearly increase in the number of patients, it is more than likely that a new hospital will be planned, and the district to be selected will undoubtedly be that including Saratoga, Washington, Essex, Clinton and Warren counties. The Commission in Lunacy will possibly this summer examine into the availability of any sites offered in the counties mentioned and bring the matter to the attention of the legislature of 1903.

**Nurses' Movement for Registration.**—The New York State Nurses' Association completed its organization at the annual meeting in Albany, April 15: The officers elected are: President, Miss Isabel Merriitt, Cherry Valley; vice-presidents, Miss Julia Bailey, Rochester, and Miss E. J. Keating, Buffalo; secretary, Miss E. C. Santord, Rochester; treasurer, Miss Mary Brooks, Saratoga. The society is now ready to consider seriously the question of legislation for registration, which will ultimately place training schools for nurses under the supervision of the regents, establishing thereby a more uniform basis of nursing education in the state, and eventually making trained nursing a recognized profession. The nurses of Illinois and New Jersey are already organized for this purpose, with Colorado, North Carolina, Pennsylvania and Massachusetts agitating. The movement is also strong in England.

#### New York City.

**Tragedy in a Physician's Family.**—The 2-year-old baby of Dr. M. B. Lewis, East Hampton, picked up from the floor of its father's office some strychnin pills that had been dropped and swallowed them. The child died as its father reached home.

**Bellevue Training School Loses Superintendent.**—Miss Agnes S. Brennan, superintendent of the Bellevue Training School for Nurses, after having been connected with that institution for about twenty years, has resigned in order that she may take a long and much-needed vacation. Her successor is Miss Delano.

**Commitment of Insane to Bellevue Hospital Illegal.**—An order has been issued from the special term of the Supreme Court directing the release of one Peter McKenna from commitment in the Manhattan State Hospital, on the ground of illegal commitment. The decision is of importance, because it makes the present procedure of commitment to Bellevue Hospital illegal.

**Medical Student a Suicide.**—Daniel D. Rosenberg, a young medical student in his third year at the College of Physicians and Surgeons, was found dead in a bathhouse, having swallowed carbolic acid and inhaled illuminating gas. His health had failed after an attack of appendicitis, and various complications had undermined his health, and in a fit of despondency he ended his life.

**Reception to Dr. Lange.**—A reception to Dr. Frederick Lange, who sails for Europe May 15, was given May 2, by his friends, all of whom had earned academic degrees in Germany. According to the customs of old "color-students" the banquet was an old-fashioned "Kommers." Dr. Lange intends to settle near Lonkoisz, West Prussia, to take charge of his estate there, which is an heirloom in his family.

**A Modern Day Nursery.**—The Virginia Day Nursery, the oldest place of its kind in this city, has just moved into a beautiful new building at 632 East Fifth Street. The structure is fireproof, is well supplied with light and air, has cement floors and white enamel furniture, a ventilating room for the children's clothes and two playgrounds on the roof, an open one for nice weather and one enclosed in glass for cold or wet days.

**Dr. A. Jacobi Retires from Professorship.**—After thirty-two years of active teaching, Dr. A. Jacobi, at the ripe age of 72, retires from the College of Physicians and Surgeons, full of years and honor. In 1860 the first chair of diseases of children was established in America, in the New York Medical College, with Dr. Jacobi as professor, and in 1865 he became clinical professor of that subject in the College of Physicians and Surgeons.

#### Buffalo.

**The Buffalo Ophthalmological Club** has been organized.

**Bed Endowed.**—The Transportation Club of Buffalo has given \$1000 to the Buffalo General Hospital for the endowment of a bed.

**The consumption hospital** which was built to replace the one destroyed by fire two years ago is completed. The building cost \$49,900, and its equipment \$5000 more. It has accommodations for 54 patients, which can be increased to 70. The building is two stories in height.

**Emergency Hospital Changes.**—Dr. J. H. Dewees, house surgeon, has resigned and will practice in Buffalo. Dr. Charles Southworth, medical officer, becomes house surgeon. Dr. McKay Hull, ambulance surgeon, is made medical officer. Dr. Gallagher, a recent graduate of the University of Buffalo, will be made ambulance surgeon.

**University of Buffalo Commencement.**—The fifty-sixth annual commencement of the medical department of the university was held May 2. Dr. John Parmenter presented the class, which numbered 38, to Chancellor, the Hon. James O. Putnam, who conferred the degrees. Dr. Matthew D. Mann administered the Hippocratic oath. Rev. David J. Burrell, D.D., New York, delivered the address on "The Doctor's Creed."

#### PENNSYLVANIA.

**Crusade Against Unregistered Doctors.**—A crusade against unregistered physicians in Allegheny county has been begun. There are 112, it is said, all of whom are to be prosecuted.

**Gift to Sanitarium.**—After visiting the White Haven Sanitarium of the Free Hospital for Poor Consumptives and seeing for himself the admirable work which is being done there in behalf of sufferers from tuberculosis, Henry Phipps, a member of the Carnegie Company, presented the Hospital with \$2500.

**Epidemic Disease.**—Homestead has from 150 to 200 cases of typhoid fever, for which the Monongahela river water is blamed.—Clifton has so serious an epidemic of scarlet fever and has paid so little attention to sanitary precautions that the State Board of Health has threatened to place the entire town in strict quarantine.

#### Philadelphia.

**Samaritan Hospital's Corner-Stone Laying.**—Interesting exercises characterized the laying of the corner-stone of the new building for the Samaritan Hospital, at Broad and Ontario streets, May 3. Addresses were made by Rev. Floyd W. Tompkins, D.D., Rev. Russell H. Conwell and others.

**The commencement exercises** of Jefferson Medical College will be held in the Academy of Music, May 29. The Alumni Banquet will take place the previous evening at the Art Club. The Commencement exercises of the Medico-Chirurgical College occur May 24 at the same place. The Rev. Dr. Harris, President of Bucknell College, will deliver an address.

**Reception at Medico-Chirurgical Laboratories.**—The informal opening of the new laboratory of the Medico-Chirurgical College took place May 1. Ex-Judge Paxson, president of the Board of Trustees, and Professor E. J. Houston, Professor L. Webster Fox, chairman of the Building Committee, and the deans of the various departments delivered short addresses.

All the faculty and a large number of the students and their friends were present and inspected the handsome and well-equipped building. The new building has 100 feet front on Cherry Street and 78 feet on Eighteenth Street, and is five stories high. On the fifth floor is the anatomy and histology laboratory. On the third, chemistry; second, dental dispensary; first, general medical and surgical dispensaries. The basement will be furnished as a gymnasium, college club and reading rooms. The chemical laboratory is said to be one of the finest in the United States. The building has cost, so far, more than \$125,000, and still more must be expended on it before it is opened for the students in the fall. Arrangements have been made to give instruction to 700 students in the three departments.

#### GENERAL.

**For Indian Service Physician.**—A civil service examination will be held in St. Louis, June 3, for the position of physician in the Indian Service. From the eligibles resulting from this examination it is expected that a vacancy at White Earth Agency in Minnesota will be filled, at a salary of \$900 per annum.—*St. Louis Republic*.

**National Health Bill.**—The Senate Committee on Public Health and National Quarantine directed a favorable report upon the Perkins Bill Monday, after very careful consideration. This is the bill making the U. S. Marine-Hospital Service a National Board of Health. Some few amendments were made, which did not affect the value or character of the bill.

#### Smallpox.

**Illinois:** Springfield has at present 12 houses under quarantine and 24 patients at the isolation hospital.

**Chicago:** Through the statement of the smallpox situation published in the latest issue of the United States public health reports, the Chicago health department is enabled to show the result of the campaign against this disease, begun last February, in the 600,000 square miles, and among the 25,000,000 inhabitants of the territory immediately tributary to Chicago. The statement covers the 17 weeks between Dec. 28, 1901, and April 25, 1902.

At the preliminary conference of railway managers and surgeons held at the instance of the commissioner January 31, it was shown that in the thirty days following Dec. 28, 1901, there had been an increase, compared with the corresponding period of 1900-1901, of more than 900 per cent. in the number of cases of smallpox reported in the group of 10 states of which Illinois is the southern center. In the remaining 33 states and territories reporting, the increase was only 26 per cent.

Between January 31 and April 25 of this year the statement shows a total of 10,598 cases reported in the Chicago territory, as against 10,464 during the corresponding period a year ago—an increase of little more than 1¼ per cent. during the last 13 weeks, as compared with the 911 per cent. increase of the first four weeks.

That this marvelous reversal of figures is due to the work so intelligent and vigorously prosecuted by the railway managements and many of the health authorities is demonstrated by the fact that during this last period of 13 weeks there have been reported 7901 smallpox cases in the remainder of the country outside the field of this work, as against 6793 cases last year—an increase of 16 per cent.

The commissioner tenders his congratulations to those who have made this showing possible by their co-operation in carrying out the details of the plan formulated at the January meeting—the essence of which was a propaganda of true vaccination, as defined in the "Vaccination Creed" of the department.

Only five new cases of smallpox were discovered in the city last week, three of them being imported from Des Moines, Iowa, Whiting, Ind., and Oak Park, Ill., respectively. During the week 17 were discharged, recovered, from the Isolation Hospital, and 33 remain under treatment. Between January 1 and April 26 there were 153 cases in Chicago, with one death.

**Indiana:** A railroad contractor's camp, at Grant, has been quarantined on account of two cases of smallpox.—The health authorities of Terre Haute have decided to prosecute physicians who fail to comply with the law in regard to smallpox cases. Several instances of such violation have come to the notice of the board and it is felt that an example should be made of the offenders.

Pesthouses were denounced by Dr. Newton A. Warner, Indianapolis, at the smallpox conference recently held there. He said that he had been all over the country and had not seen a pesthouse fit to keep a sick dog in. No one would want

his wife or children to be confined in a pesthouse with a lot of dirty, lousy vagrants.

Iowa: Several additional cases have appeared in Davenport.

Kentucky: The Kentucky State Board of Health, at a meeting April 25, decided that, unless the Indiana health authorities take prompt and vigorous measures to stamp out smallpox, which is now prevalent in that state, it would establish a quarantine at the Ohio river and allow no one to cross to the Kentucky side unless vaccinated. The meeting was the result of a conference at Indianapolis yesterday between the Indiana and Kentucky boards of health, at which nearly all the health officers from the former state were present. The situation, as shown by yesterday's conference, is most alarming. In 60 of the 92 counties in Indiana, smallpox is prevalent, and in one county—Delaware—there are said to be 500 cases of the disease. To make the situation worse the Indiana State Board of Health is entirely without funds to attempt to prevent its spreading, and the state has no "epidemic fund," as is provided for by statute in Kentucky.

Maryland: A man suffering from smallpox was taken to quarantine April 29. The health commissioner estimates that each case of smallpox costs the city nearly \$300. The case must be taken to quarantine, and there fed and nursed. His bedding and clothing must be burned and replaced. The house must be quarantined and a guard stationed there. Those in the house must be fed, and all in contact with the case provided with new clothes, so that those worn may be burned.—Smallpox has broken out among the soldiers at Fort Howard, at North Point on the Patapsco, below Baltimore, a case developing May 1.—Dr. C. L. Cunningham, Cresaptown, has the smallpox, having contracted it at Pinto, where there are nine cases.

Massachusetts: In the case of J. H. Mugford, East Boston, summoned for refusal to allow his child to be vaccinated, the defendant was found guilty as charged. The case was appealed to the Supreme Court.—Two new cases have appeared in Athol. Neither patient had been vaccinated.

Michigan: Smallpox was present at 126 places in the state during the week ended April 19.—At Ionia, only six cases now remain, all of which are strictly quarantined.

Minnesota: Seven cases were discovered at South Stillwater, April 28.

Missouri: Foreman A. H. Boles of H. F. Balch & Co., contractors for the Colorado railroad, with 14 of his men, will be arrested Wednesday and brought to Jefferson City for trial for again refusing to obey the quarantine regulations of the county board of health. County Physician Dr. J. L. Thorpe stated that all in the quarantine district had been vaccinated except Boles and his force, and that warrants would be issued at once for them. Boles and three of his men were fined a few days before for refusing to obey the quarantine regulations, but they returned to work, defying the order of the board, and they will again be arrested for this offense.—Greene County now has 18 cases under quarantine.

Nebraska: Reports have been received at West Point from Lincoln township that the inhabitants of that community are having a serious seige of smallpox. All persons living in the stricken district have been ordered vaccinated and all families are under strict quarantine.

The smallpox report for the week ended April 26 shows but 45 cases of the disease in the emergency hospital at Omaha and throughout the city.

New York: The State Department of Health Bulletin reports smallpox in the Adirondacks as follows: At Old Forge and Portow, Herkimer County, 5 cases; Tupper Lake and Dickinson, Franklin County, 25; Hopkinton and Edwards, St. Lawrence County, 16; Crogan, Lewis County, 2; Newcomb, Essex County, 4; Champlain, Chazy, Plattsburgh and Saranac, Clinton County, 8, and 4 or 5 in the towns of Albion and Richland, Oswego County—about 75 cases in all. During April 5 cases occurred at Mt. Vernon, Tarrytown, Mamaroneck and Islip, near New York City; 12 cases have developed in Albany and 2 at Troy, and 1 at Auburn.

Olean reports 4 cases and Islip, Long Island, has several cases.—Between January 1 and April 26 there were 895 cases of smallpox in New York City, with 175 deaths.

Pennsylvania: Pittsburg now has more patients than at any time during the past year. The patients now number 38.

South Dakota: O'dham has 15 cases in town and a number in the surrounding country. Quarantine is contemplated.

Canada: The Montreal *Sun* makes editorial comment on the value of vaccination as follows: The great value of vaccination has been proved in a striking manner by a report issued by the Medical Health Officer, as to the outbreak of

smallpox in this city. The disease broke out last autumn and from that date till April of this year there have been over three hundred cases of smallpox. Of this entire number only three had good vaccination marks on their arms. In fact only 1 per cent. of those who have been vaccinated contracted the disease. Could anything be more striking than this? The outbreak has cost the city tens of thousands of dollars, and besides this valuable lives have been sacrificed; and the cause of this is entirely due to the antipathy, on the part of unnumbered persons, against vaccination. Surely the history, as to wonders vaccination has worked during the past century and a half ought by this time to have impressed the entire civilized world with the truth that vaccination is a direct preventive against one of the most dreadful scourges that afflict humanity.

Porto Rico: There are about 150 cases of the disease at Arceibo at present, and an effort will be made to quarantine all as soon as discovered. It is thought that it will be impossible to get the epidemic under control until all cases are isolated. The hospital was finished April 22, and has a capacity of 60 beds. A building next to the regular hospital will also be used as a varioloid hospital. It will accommodate 26 patients.

#### CANADA.

**An Editor's Resignation.**—It is understood that Dr. H. B. Anderson has handed in his resignation as editor of *The Canada Lancet*.

**Winnipeg General Hospital.**—The number of patients treated in the Winnipeg General Hospital during the week ending April 26 was 218, of whom 133 were men, 58 women and 27 children.

**Personal.**—Dr. Dryer has been added to the hospital staff of the City Hospital, Vancouver, B. C.—Dr. Rose, who has been house surgeon at the St. Boniface Hospital, Winnipeg, for the past year, has commenced practice at Gladstone, Man.

**Western University, London, Ontario.**—The results of the examinations in the Medical Faculty of the Western University at London, were posted on May 1. Fifteen will receive the degree of M.D. The past session has been a successful one and has given great satisfaction to the faculty.

**Compulsory Vaccination.**—The Provincial Board of Health of Quebec has again called upon the City of Montreal to pass the obligatory vaccination by-law under compulsion of a heavy fine. It is understood that Alderman Ames has one ready, which will shortly be brought before the city council.

**Undesirable Immigration.**—The Canadian Immigration Act is being amended to provide for the prohibition of certain diseased immigrants. The clause reads: "Such prohibition may be absolute or may be accompanied by permission to land for medical treatment only, for a period that may be determined by the order or proclamation."

**Mortality of Infants in Montreal.**—During July and August of last year there were times when two hundred babies died per week. In order to prevent a repetition of this excessive mortality steps are being taken to organize a local society for the purpose of instructing young mothers as to the care of their infants. Dr. Laberge, the medical health officer, will take a prominent part in this movement.

**Dalhousie University, Halifax.**—Convocation at Dalhousie University was held on the afternoon of April 29. The past session has seen the largest class in medicine in the history of the university: 27 young gentlemen received their M.D. and C.M. degrees. Mr. A. R. Cunningham, a son of Dr. Cunningham of Dartmouth, N. S., won the gold medal in the primary examination, while Mr. S. A. Fulton of Truro received the gold medal in the final.

**Two New Sanitariums.**—As a result of the recent tuberculosis conference held at Ottawa, two gentlemen have offered to build two sanitariums at their own expense. One is Sir William Macdonald of Montreal, and the institution will probably be situated in the neighborhood of that city; the other is the newly elected president of the association, Mr. W. C. Edwards, M. P., of Ottawa, whose sanitarium will be in the neighborhood of the capital.

**A Montreal Physician Honored.**—Dr. James Stewart, who holds the Chair of Medicine and of Clinical Medicine at McGill University, has been elected president of the Association of American Physicians, which met in Philadelphia, recently. Dr. Stewart is a graduate of McGill and a licentiate of Edinburgh. He was professor of materia medica at McGill from 1883 until 1891, when he was promoted to the chair which he at present holds.

**Samaritan Free Hospital, Montreal.**—The annual meeting of the Samaritan Free Hospital for Women was held last week in Montreal. The past has been a prosperous year. One hundred and thirty-three patients received treatment, an increase of twenty over the previous year. Outside the hospital two hundred patients were supplied with remedies and advice. Of the total number treated, there were five deaths, a decrease in comparison with the previous year. According to the report of the treasurer the year commenced with a balance of \$455.52. The receipts amounted to \$3,733.74, while the expenditure was \$3,149.75.

**A Deadlock Re Civic Hospital, Montreal.**—Montreal does not seem to know where it is at with regard to the erection of a new contagious diseases hospital. A short time ago it was given out that the matter had been finally and ultimately adjusted, but the archbishop would not accept for the Catholics a single institution; so now there is a proposition before the city council to the effect that the Notre Dame Hospital and the Royal Victoria Hospital erect smallpox hospitals and receive a stated sum per annum for the care of such patients. The hygienic committee will make no recommendations until the above is settled by the city council.

#### FOREIGN.

**Suit Against a Russian Surgeon.**—Dr. Modlinski was condemned by the court at Moscow to seven days' imprisonment for performing an operation without the consent of the patient. He appealed to a higher court, which has confirmed the sentence.

**Death of Hans von Hebra.**—The famous professor of dermatology at Vienna, Hans von Hebra, died in that city, April 13, in his fifty-fifth year. He was the worthy son of the founder of the chair of dermatology at Vienna, Ferdinand von Hebra, and was the author of more than 30 articles and works, principally on this specialty.

**Nature-Healer Endowment.**—The will of a recently deceased official at Vienna bequeaths \$100,000 for the construction and endowment of a nature-healing sanatorium. Only nature-healers are to be in charge and all graduated physicians are to be excluded. The authorities at Steiermark, where the sanatorium is to be erected, have made no objections, but the local physicians have entered a formal protest against the project and appealed to the Minister of the Interior.

**The Riberi Prize.**—The Turin Academia di Medicina announces that the Eleventh Riberi Prize of about \$4000 will be awarded for the best work produced during the years 1902-1906 in the field of the medical sciences. Other points being equal, the preference will be given to works which have in view the amelioration of the hygienic conditions of Italy. Competing works must be in French, Italian or Latin, and must be received by the secretary, B. Silva, before the close of 1906.

**Other Deaths Abroad.**—Vienna has also lost J. Habart, who died, April 19. His name is best known by his works on military surgery. The death is reported of Dr. G. Inzani, ex-professor of pathologic anatomy at Parma; B. Robert, professor of clinical medicine at Barcelona; H. Schobl, professor of ophthalmology at Prague; E. Fazio of Naples, editor of the *Rivista Internazionale d'Igiena* and author of numerous works on hygiene and bacteriology. The Paris medical school has also sustained a severe loss in the death of B. Rendu, professor agrégé, whose name is familiar to the readers of current medical literature.

**Thomas Moore Madden, M.D.** (Hon. Causã) Texas Med. Col., M.R.C.P. Ire., F.R.C.S. Edin., M.R.C.S., Eng., who was for many years one of the prominent practitioners of Ireland, died April 16, at Tinode, aged 64, after a long illness. He had served as attending physician to Rotunda Lying-in Hospital, and Mater Misericordiae Hospital, consultant to the Children's Hospital and National Maternity Hospital; vice-president British Gynecological Society, president of the Obstetrical Section of the British Medical Association, Fellow of the Obstetrical Society of Edinburgh, corresponding member of the Gynecological Society of Boston, examiner at Queen's University of Ireland, Royal University of Ireland, Royal College of Surgeons in Ireland and Apothecaries' Hall of Ireland, etc. He was the author of numerous books and other contributions to medical literature and as well some historical and literary works. He was a highly-esteemed and honored surgeon and a popular teacher. His personality will long be missed from Dublin medical circles.

**Von Leyden's Anniversary.**—The Germans celebrated Von Leyden's 70th birthday with much ceremony, April 20. The

session of the Congress of Internal Medicine at Wiesbaden, April 16, was an actual Leyden festival. His efforts in founding the Committee of Cancer Research, in promoting the founding of sanatoria for consumptives and his well-known achievements in the pathologic anatomy of spinal affections and multiple neuritis have carried his fame far and wide. His name is connected with that of Charcot in the Charcot-Leyden crystals; he has devoted immense energies of late years to the development of hygieno-dietetic therapeutics. The celebration of his birthday was not confined to the profession and the appreciation of official and lay participants, as one exchange remarks, is an encouragement for all humble practitioners to live up to their high ideals as preachers and promoters of hygiene and protectors of the public welfare. An endowment was founded in Leyden's name for the encouragement of medical research, another for seaside sanatoria for children and a third for a foundling asylum. A portrait bust was also unveiled, to be placed in the grounds of the Charité, where a bust of Griesinger was recently installed.

#### LONDON LETTER.

##### The Smallpox Epidemic.

There are 1431 patients in the metropolitan smallpox hospitals, against 1526, 1522 and 1437 in the three preceding weeks; 328 new cases were admitted in the week against 389, 376 and 274 in the preceding weeks.

##### Smallpox in Scotland.

In Scotland for the quarter ending March 31, 614 cases of smallpox occurred, of which 391 were in Glasgow. The monthly figures are as follows: January, 75; February, 207; March, 322. From April 1 to 15, inclusive, the number was 75, of which Glasgow contributed 31.

##### Revised Classification of the Causes of Death.

The Registrar-General has issued a new official list of the causes of death, which contains the most important modifications which the advance of science has rendered necessary. Up to the end of the last century—for a period of 60 years—the list of causes of death used was that compiled by the father of English vital statistics, the celebrated Dr. Farr. With the beginning of the new century the list was revised in accordance with the "Nomenclature of Diseases" of the Royal College of Physicians, and a copy is now being issued to all medical practitioners. Such time-honored titles as "zymotic," "miasmatic," "constitutional," "developmental" and "dietetic" have been discarded and the diseases classed under these names have been aggregated under the heading of "General Diseases." In the grouping of these general diseases there are several important improvements. Thus, malignant disease has been subdivided into (1) carcinoma, (2) sarcoma and (3) such cases as cannot with certainty be assigned to either class, for which the term cancer may be used. Italics are used for names which are to be discouraged, but the use of which is at times unavoidable. Thus the College of Physicians is convinced that the terms "gastro-enteritis," "muco-enteritis," "gastric catarrh," etc., which are commonly employed to designate the disease officially known as epidemic diarrhea, are misleading and cause the specific nature of the disease to be ignored. The confusion of terms renders impossible the accurate determination of the prevalence of the disease at special times and places. But as physicians are loth to use the term diarrhea on death certificates, probably because the public regard it as implying a mild disease insufficient to cause death, the term epidemic enteritis or zymotic enteritis is authorized. Dropsy must not be returned as a cause of death without some indication of its probable origin in disease of the heart, liver, kidneys, etc. The term puerperal fever should no longer be used; pyemia, septicemia, or sapremia in a puerperal woman should be substituted. Phthisis is condemned as an ambiguous term which sometimes denotes other wasting diseases than tuberculosis; tuberculous phthisis or pulmonary tuberculosis should be used. Similarly, tabes mesenterica should not be used, as it frequently denotes other diseases than tuberculous peritonitis, which is the authorized term. In returning hydrocephalus those cases due to tuberculosis should be distinguished. Congenital hydrocephalus should always be returned as such. It is hoped that the indefinite term "convulsions" will be restricted to those cases in which the true cause can not be ascertained. At present more than 11 per cent. of the total deaths of infants under one year are referred to convulsions simply. The classification of deaths would be much simplified, it is said, if brain paralysis were always distinguished from paraplegia. The terms "hemiplegia" and "apoplexy" are condemned as only denoting symptoms. They should be replaced by such as signify definite lesions, e. g., "cerebral hemorrhage." Three

different kinds of pneumonia—lobar, broncho-, and epidemic now appear. A wish is expressed that the use of the term "croup" to designate non-diphtheritic affections of the larynx or trachea should be abandoned.

#### New Regulations for the Naval Medical Service.

The new regulations are similar to those recently introduced for the army and described in *THE JOURNAL*. The entrance examination is made more practical and clinical. A competent knowledge of operative surgery will be essential for candidates and will be tested by operations on the dead body. Rank as staff surgeon will be granted to surgeons 12 years from the date of entry, provided they pass the requisite examination eight years after entry. The subjects of this examination will be medicine, surgery, pathology, general hygiene and naval hygiene. The rates of pay are considerably improved. Thus on entry a surgeon receives per annum \$1270, after four years' service \$1550, after eight years \$1825; a staff surgeon \$2190, after four years' service \$2460; a fleet surgeon \$2735, after four years' service \$3010, after eight years' service \$3285; a deputy inspector-general \$3830, an inspector-general \$6500. Every officer will have the option of retiring after 20 years' service on a pension of \$5 a day. Every medical officer must undergo a post-graduate course of three months at a metropolitan hospital once in eight years.

#### The Eradication of Malaria.

Major Ronald Ross has submitted a very satisfactory report on the anti-malaria work of the expedition to West Africa, despatched from the Liverpool School of Tropical Medicine. At Freetown, Dr. Logan Turner, employing about 70 men, has drained nearly the whole of the most pestilential parts of the town. The areas dealt with were formerly full of hollows, pits and ill-made drains which in the rainy season contained stagnant pools breeding swarms of mosquitoes. A gang of men was also employed to collect old tins, bottles and other rubbish from the houses, and 2257 cart-loads of such refuse have been removed and 16,295 houses visited. In Dr. Ross' opinion the possibility of ridding Freetown and therefore any town of mosquitoes has been demonstrated. The change in the demeanor of the Europeans is striking. Two and one-half years ago, when Dr. Ross visited the town, he never saw a more gloomy place. The inhabitants felt as if a sword were hanging over their heads. All this is changed and they are as cheerful as the Europeans in India. Arrangements have been made for Dr. Taylor to proceed to Cape Coast in order to start anti-malaria work there, as the mortality is very high.

#### Cancer Research.

To carry out the scheme of cancer research which has been described in *THE JOURNAL*, an appeal, signed by Sir William Broadbent, Sir Douglas Powell, Sir Thomas Smith, Mr. A. Balfour, First Lord of the Treasury, and other prominent social personages, has been published. Five hundred thousand dollars are required. Of this sum \$100,000 has been paid or promised. As soon as \$150,000 are collected the scheme can be put into force. As it is thought that the investigation must extend over a considerable number of years, in order to secure continuity of research, a capital of \$500,000 is required.

## Correspondence.

### Puerperal Infection in Private Practice.

CHICAGO, April 22, 1902.

*To the Editor:*—Your editorial in *THE JOURNAL* of April 19 on "Puerperal Infection in Private Practice" calls attention to a very important subject and one that will bear much discussion to bring and keep it properly before the profession. A careful inspection of the mortality reports of the various city boards of health will confirm the content of your statement, which I believe is also in agreement with the impression of physicians who are particularly interested in obstetric work: that puerperal infection in private practice is still much larger than it should be and not on the decline. In your statement of the causes of this unfortunate state of obstetric practice, however, it may be that you have not dwelt with sufficient fulness nor with sufficient emphasis on the chief factors. At any rate further consideration of these factors is desirable if we expect to bring about any improvement.

I can not hope, in a brief letter, to enter into a comprehensive discussion of this subject, but I wish to call attention to two or three points that have an important influence in re-

tarding the development of universal clean obstetrics. The first is the general lack of preparation for managing a case of labor. A clean bed, well protected with rubber sheets or clean oilcloth, plenty of clean sheets and towels to prevent the soiling of the bed, clean basins and pitchers, with clean soap and nail brush and file and sublimate tablets for use in cleaning the physician and the patient, plenty of sterilized gauze and cotton for dressings in the puerperium, are needed for the proper management of a labor case. How often does the physician neglect to order or provide for these necessary preparations and rues their lack when he comes to the case and finds no impervious covering for the bed or no clean soap or bowl that he can use in washing his hands. Especially in pathologic or operative cases are these preparations necessary. In postpartum hemorrhage, an unlimited supply of hot water for douches, with a rubber sheet to act as a drain, are necessary, and their lack may cost the life of the patient or be an important element in a subsequent infection. In operative cases a table (kitchen) and a good light are necessary, beside the necessary instruments for repair, etc. It is well known that most of the cases of bad infection are the operative cases. This is largely due to the fact that operations are undertaken without proper preparation. Operations are made on the bed without a good light, without anesthesia, under conditions that make any good work absolutely impossible because of the failure of the physician to properly prepare what a surgeon would absolutely demand as essential for a much less important case. The results are dangerous risks and unnecessary infection.

A second cause of poor obstetric work is the hurry in which the work is done, the desire of the obstetrician to get through the case as soon as possible. Many physicians dislike to remain quietly with a case and watch it proceed undisturbed, interfering only when dangerous symptoms demand interference. They feel that their time is wasted unless they are doing something to help on the labor. This attitude of mind leads to imperfect sterilization of the hands and preparation of the patient, frequent examinations, efforts at manual dilatation of the cervix, premature rupture of the membranes, premature application of forceps without dilatation of the cervix or proper indication for artificial delivery, hasty extraction or expression of the placenta and superficial inspection of vulvar and vaginal wounds to avoid the repair of probable lacerations. This haste in the management of labor, this impatience for nature's processes, whether it proceeds from the pressure of other engagements or from the inadequate remuneration, works to the great danger of the patient and is no doubt one of the most important causes of puerperal infection.

Closely allied to the subject of hasty obstetric work is that of the insufficient compensation which is almost universally given physicians for the management of cases of labor. This has an important bearing on the quality of work done and thus on the question of infection. There is no doubt that obstetric fees are in general ridiculously low and made on a very harmful basis. The common practice of taking charge of a case during pregnancy, labor and child-bed for a certain fee is unjust both to the patient and the physician. Why should one agree to take charge of a case for a certain fee not knowing whether the labor will last two hours or two days? The result of this practice is to induce the physician to hasten the labor with the results just alluded to. How can a physician be expected to watch a case carefully and patiently when he knows that his fee for twenty hours of work which have kept him from his sleep and his office and other practice will be \$10, this also including his compensation for previous and subsequent visits? It is no doubt true that much of the obstetric work pays less than 50 cents an hour, less than the wages of a carpenter or plumber. A more reasonable compensation for obstetric work and a more just basis of compensation for such work is a very important condition of an improvement in its character.

Any particular proposition to improve obstetric practice must take into consideration these factors of poor work. It will be seen that an important sociologic problem is involved—one that is of great interest to the profession at the present

time—for its solution depends upon the success of medical organization.

Yours truly,

C. S. BACON.

SO. NORRIDGEWOCK, MAINE, April 29, 1902.

*To the Editor:*—In your issue of April 19, you voice the sentiment, editorially, that the "mortality, in private practice, from puerperal sepsis is greater to-day than in the pre-aseptic period."

It seems to me that this statement is altogether too sweeping in its nature, and that a careful investigation will not bear out the allegation.

For one, I can say that in five years in this field of 1800 people, with three practitioners, neither better nor worse than the average country doctor, there have been no deaths from puerperal sepsis, nor from any diseases that might have resulted from even a slight sepsis. I am very much inclined to think that Dr. Wiggin's statement and your editorial comment are overdrawn.

E. GARD EDWARDS.

#### Unfair Deductions from Statistics.

DAVENPORT, IOWA, April 28, 1902.

*To the Editor:*—In the volume of papers and reports just issued by the American Public Health Association, the deaths from typhoid fever during the years 1898, 1899 and 1900 in 135 municipalities are given under the misleading title, "Typhoid Fever Death-Rates in American Cities." In the interest of accurate statistics and the fair fame of many of the cities misrepresented by this title, I wish to enter a vigorous protest against the article in question.

The rates given are based on but three years' data, and those are the least representative of local conditions that could possibly have been selected. In them was observed, all over the Union, a marked increase of enteric fever due to no change in local conditions, but scattered broadcast by returning soldiers from the Spanish war. It is unjust to select this particular brief period to show the typhoid death-rate of American cities; and it is unfair to use these rates, as has been done, in a comparison of methods of water filtration.

If, instead of three we take ten years, ending with 1900, the typhoid death-rate for this city has been but slightly over 21 instead of 32 per hundred thousand, as given. With an average population since 1900 of at least 32,000 our typhoid deaths in the ten calendar years have been but 68, making our rate as above 21.25. Even this figure is too large for our average rate inasmuch as it includes the abnormal importation period of the war.

Respectfully, C. H. PRESTON, M.D.

#### Miscellany.

**Causation of Beri-Beri.**—In the reports of sick for January and February, 1902, recently received at the Surgeon-General's office, Washington, D. C., from the prison and beri-beri hospital at Lingayen, Pangasinan, P. I., Captain Harry A. Littlefield, asst.-surgeon, U. S. Vols., has the following interesting note on the causation of beri-beri: Since the establishment of this prison until February 1 of this year, the native prisoners have been supplied with Chinese white rice. During this time beri-beri has been markedly endemic in the prison. The records of this office show that the number of deaths have averaged five monthly, while the number of new cases monthly averaged twenty. When prisoners reported sick with beri-beri they were removed from the prison to a building about one-half mile from the prison, the upper story of the building used for a hospital. The difference between conditions existing at the beri-beri hospital and the prison being only the higher elevation of the former; the diet supply was the same at both places. Many of the cases at the beri-beri hospital continued to grow worse and died. The majority of those who did recover, did so after a very long illness and many of them suffered from numerous relapses. During the month of January there were thirty-five cases in the beri-beri hospital and as many who were slightly affected in the prison. The sanitary conditions were excellent. In the civil prison, not

more than one-quarter of a mile distant, there were confined a large number of natives, the sanitary condition not as satisfactory as those of the military prison, they were more crowded, in poorer buildings and not in the open air any more than the natives confined in the military prison. In this civil prison there were no beri-beri cases, the only difference existing in favor of the civil prison being that the ration was purchased in the open market. At the beginning of February of this year, upon the recommendation of the prison surgeon, the use of the Chinese white rice supplied by the commissary was discontinued and native rice from the open market purchased in its place. Since that time no new cases of beri-beri have developed and no death has occurred. Of the 29 cases remaining in hospital on the last of January, 16 have been returned to duty; 8 released, greatly improved; 5 remaining, greatly improved and still improving. The mild cases in the prison have all recovered. This marked change occurred in the space of one month, the only apparent difference existing during this period and in the previous times being that of the rice supply. From these facts it would seem that the cause of beri-beri in this prison has been brought about by the use of the Chinese rice, white variety.

**The Recent Operation on the Xiphopagous Twins.**—The Orissa twins have long attracted the interest of scientists. Baudouin published an illustrated description of them in the *Semaine Medicale*, in 1892, p. 474. He stated that 9 cases of this kind are known, all girls except the Siamese twins. Three of the pairs died soon after birth; 3 were successfully operated on with the survival of one or both twins, and since 1892 Chapot-Prevost and Doyen have each performed the operation of separating xiphopagous twins with the survival in health of one twin. The mother of the Orissa twins had previously borne five children, the oldest now 28, and since the birth of the twins, in 1889, has passed through another pregnancy. Her other children are normal. It is a curious fact that 3 out of the 9 known cases came from Southern Asia. Doyen presented the details of his operation at the Paris Académie de Médecine, April 8. He mentioned that the twins had not been united by any supplementary tissue. The union was as if an incision had been made in two normal children from the ensiform cartilage to the umbilicus, and the corresponding raw surfaces of liver, diaphragm, ensiform cartilage and skin had been approximated and sutured together. The pedicle was merely the result of traction. At the back it was no more than a groove, but in front it was 5 or 6 cm. wide by 10 or 12 in height. When the twins faced about the pedicle acted like a hinge, the back becoming a groove and the front stretching to the above size. The umbilicus was in the center of the lower edge of the pedicle. The presence of three large arteries in the hepatic pedicle in Doodica and the fact that Radica seemed always to thrive at the expense of her sister, and that the latter exhibited much greater resistance immediately after the separation, seemed to corroborate the assumption that Radica received arterial blood in abundance from Doodica while she returned to her only venous blood. The operation was performed to save Radica's life, as Doodica was in an advanced stage of tuberculous peritonitis. The former had exhibited tuberculous ganglia before the latter's peritonitis developed. The methylene blue test, made on Doodica before the operation, showed that the interchanges were very rapidly accomplished. Doodica's temperature was 102.4, while Radica's was only 99, which fact is another refutation of the "humoral theory" in regard to fever. Doyen believed that the least loss of blood would have been fatal and safely avoided it by the application of his "eeraseur" which crushed and clamped the stump of the liver on both sides. The stump was sutured with the wall, leaving two wicks of gauze in each wound to warn off hemorrhage. The results were perfectly satisfactory. The autopsy of Doodica, who succumbed to her peritonitis, showed that all the organs were in normal position. Radica has gained more than 12 pounds since the operation, February 9. The tuberculous ganglia in neck and axilla have been extirpated and she seems to be thriving, although affected with pronounced lateral curvature in the dorso-lumbar region of the spine. This curvature is evidently due to the constrained position which she had

been forced to assume, and is an argument in favor of early intervention in such cases, before the complete development of the skeleton. The accounts of the operation in the lay press all slyly add that champagne was given in abundance after the intervention was finished, referring to the original source of Doyen's wealth, his father's champagne vintage. For those interested in xiphopagi we refer them to the Institut de Bibliographie, Paris, Boul. St. Germain 93, which makes a specialty of loaning its collection of photographs, cuts, etc., with or without the accompanying abstracts, to any part of the world. It announces that it has pictures of 50 typical specimens of such monstrosities. Chapot-Prevost's operation was described and illustrated in *THE JOURNAL*, XXXV, p. 1248, 1307 and 1379. The surviving twin was in good health when she called recently at the office of the *Brazil-Medico*, at Rio.

## Association News.

### Railroad Rates for Saratoga Meeting.

At this writing, May 3, all of the railroad associations except the Southwestern Passenger Bureau have agreed to the following rate for the Saratoga Meeting of the American Medical Association, viz.: one fare and a third on the certificate plan, with return limit July 2 on payment of a fifty-cent execution fee and deposit of certificates with Saratoga railroad agent, not later than June 17. To those beginning the return trip not later than June 17, no fifty-cent extra fee will be charged. This rate has been extended to the American Academy of Medicine, which meets at Saratoga, June 7 to 9, therefore tickets will be on sale in the Trunk Line territories and proportionately early in other territories from June 4 to June 13. Those attending the meeting must secure a certificate from the local railroad agent when they purchase their ticket to the meeting, and the certificate thus obtained, in order to be honored for return trip reduction, must be presented to Dr. William E. Swan, at Saratoga, on either June 11, 12 or 13 for signature and endorsement. Members failing to observe this precaution will not be granted any reduction in the cost of the return ticket. From recent correspondence with the Southwestern Passenger Bureau the committee feels confident that that association will agree shortly to the rate of the other associations herein quoted. The Transportation Committee has been in active correspondence with the several passenger associations on the subject of rates for the Saratoga Meeting since January last, but has been unable before this date to receive positive assurances in the matter of rates.

H. L. E. JOHNSON, M.D.,  
Chairman Committee on Transportation.

### New Members.

The following is a list of new members for the month of April, 1902:

| ARIZONA.                             | DISTRICT OF COLUMBIA.          |
|--------------------------------------|--------------------------------|
| Fenner, H. W., Tucson.               | Jung, F. A. R., Washington.    |

**Preliminary Programs of the Sections of the American Medical Association, Saratoga Meeting, June 10-13, 1902.**

The following is a list of papers to be read in the various sections. The programs as arranged below must be considered as preliminary, and the order given not necessarily to be followed in the official program.

The official program will not be ready for distribution till the meeting.

Write to the Secretary of the Section in regard to any changes, corrections, etc., and not to THE JOURNAL.

**Section on Practice of Medicine.**

Chairman, Frank A. Jones, Memphis, Tenn.; Secretary, Robert P. Preble, Chicago.

Opening Address by the Chairman, Frank A. Jones, Memphis, Tenn.

The Autogenous Diseases, Victor C. Vaughan, Ann Arbor, Mich.

Some Clinical Points in the Diagnosis and Differentiation of Ascites, Arthur R. Edwards, Chicago.

Appendicitis from a Physician's Standpoint, James Tyson, Philadelphia.

Amebic Dysentery in Michigan, George Dock, Ann Arbor, Mich.

A Case of Scurvy with Unusual Poverty of the Blood, James E. Talley, Philadelphia.

The Origin of the Vesicular Respiratory Sound, C. F. Hoover, Cleveland, Ohio.

Etiology of Chronic Nephritis, A. R. Elliott, Chicago.

Malarial Nephritis, with Report of a Case, W. Britt Burns, Memphis, Tenn.

Classification of Chronic Nephritis, James B. Herrick, Chicago.

The Diagnosis of Chronic Nephritis, A. O. J. Kelly, Philadelphia.

The Early Circulatory Indications of Chronic Bright's Disease, L. F. Bishop, New York City.

Uremic Aphasia, David Riesman, Philadelphia.

The Prognosis and Treatment of Chronic Nephritis, DeLancey Rochester, Buffalo, N. Y.

Clinical Observations on Transposition of the Viscera, Congenital and Acquired, J. R. Arneill, Ann Arbor, Mich.

Notes of a Case of Cardiac Thrombosis, J. H. Musser, Philadelphia.

Some Instructive Errors in Cardiac Diagnosis and Treatment, Richard C. Cabot, Boston.

Venesection, H. B. Favill, Chicago.

The Employment of Digitalis and Aconite in the Treatment of Cardiac Diseases, H. A. Hare, Philadelphia.

Tuberculous Myocarditis, J. M. Anders, Philadelphia.

Some Cardiac Phenomena as Revealed by the Roentgen Rays, Albert Abrams, San Francisco.

The Occurrence of Gout in the United States with an Analysis of Thirty-six Cases, T. B. Fletcher, Baltimore.

A Summary of Recent Investigations by the Author into the Causes and the Treatment of Diabetes, A. C. Croftan, Philadelphia.

On the Association of Graves' Disease and Glycosuria, Heinrich Stern, New York City.

Syphilis of the Liver, Chas. G. Stockton, Buffalo, N. Y.

Syphilis of the Stomach, Max Einhorn, New York City.

Syphilis of the Serous Membranes, Alfred Stengel, Philadelphia.

Endocarditis as a Complication of Pneumonia, E. F. Wells, Chicago.

The Treatment of Croupous Pneumonia, E. Fletcher Ingals, Chicago.

An Analysis of 65 Cases of Gastroparesis, J. Dutton Steele, Philadelphia.

The Etiology of Rheumatism and the Significance of Purpura, George W. Webster, Chicago.

Etiology and Prophylaxis of the Cardiac Manifestations of Articular Rheumatism, Joseph M. Patton, Chicago.

Primary Rheumatic Endocarditis, Judson Daland, Philadelphia.

The Salicylates in Acute Rheumatism, J. J. Walsh, New York City.

The Present Status of Serumtherapy, Frederick A. Packard and Robert N. Willson, Philadelphia.

Obstetrics and the General Practitioner, M. H. Russell, Philadelphia.

The Open-Air Treatment of Tuberculosis; Tent Life in Arizona, R. W. Craig, Phoenix, Ariz.

Lung Compression in the Treatment of Tuberculosis, A. F. Lenke, Chicago.

The Causal Relation of Blood Poverty to Gastric Ulcer, with Report of an Illustrative Case with Atypical Findings, Robert N. Willson, Philadelphia.

The Influence of Electric Ozonation Upon the Blood, G. Lenox Curtis, New York City.

**Section on Obstetrics and Diseases of Women.**

Chairman, J. H. Carstens, Detroit; Secretary, C. L. Bonifield, Cincinnati.

Chairman's Address, J. H. Carstens, Detroit, Mich.

Treatment of Retroversion and Retroflexion of the Uterus, J. W. Cokenower, Des Moines, Ia.

Vaginal Celiotomy and Vagino-fixation of the Uterus, A. Goldspohn, Chicago.

Surgical Treatment of the Utero-sacral Ligaments Through the Vagina in Retroversion of the Uterus, J. Wesley Bovée, Washington, D. C.

Electrothermic Hemostasis, A. J. Downes, Philadelphia.

Drainage in Abdominal and Pelvic Surgery, A. Palmer Dudley, New York City.

Technic of Abdominal Hysterectomy for Cancer, W. R. Pryor, New York City.

High Amputation of the Cervix versus Hysterectomy for Operable Carcinoma of the Cervix, C. C. Frederick, Buffalo, N. Y.

Operation for Recurrence of Cancer After Hysterectomy, E. W. Cushing, Boston.

Some Cases of Ureteral Stricture, H. A. Kelly, Baltimore.

Plastic Surgery of the Female Urethra, with Report of a Unique Case, H. P. Newman, Chicago.

Repair of the Perineum, C. A. L. Reed, Cincinnati.

Deflected Presentation in Labor, Gustav Kolischer, Chicago.

What Cases of Placenta Previa Can Be Best Treated by Cesarean Section? Francis D. Donoghue, Boston.

Massage and Exercise in the Management of the Puerpera, C. S. Bacon, Chicago.

The Results of Abdominal Section for the Various Forms of Septic Inflammation Following Labor and Abortion, B. C. Hirst, Philadelphia.

Etiology and Pathology of Ectopic Pregnancy, Henry D. Ingram, Buffalo, N. Y.

Cesarean Section Made Necessary by a Ventrofixation, William M. Findley, Altoona, Pa.

Is Laparotomy or Vaginal Section Justifiable or Indicated for the Relief of the Single Symptom of Sterility? J. R. Goffe, New York City.

The Influence of Prolapse of the Kidney on the Production of Pelvic Disease in the Female, A. H. Goelet, New York City.

Movable Kidney and Its Remote Results, A. H. Cordier, Kansas City.

Pathologic Conditions of the Omentum as a Surgical Factor; the Best Method of Treatment, Henry O. Marcy, Boston.

Treatment of Umbilical and Ventral Hernia, Wm. Wathen, Louisville, Ky.

Critical Remarks on the Methods of Operations in Vogue for Cyclocele with or without Prolapse of the Uterus, C. O. Theinhaus, Milwaukee, Wis.

Some of the Complications of Gonorrhea in the Female, J. Taber Johnson, Washington.

The Evolution of the Treatment of Pelvic Inflammation, E. E. Montgomery, Philadelphia.

The Mortality Following Operation for Pus in the Pelvis, Hunter Robb, Cleveland, Ohio.

Drainage Versus Radical Operation for Suppuration in the Female Pelvis, C. P. Noble, Philadelphia.

The Advantage of the Vaginal Route in Obese Patients, W. H. Humiston, Cleveland, Ohio.

Uterine Myomata, Thomas S. Cullen, Baltimore.

Post-Operative Intestinal Paresis, F. H. Wiggin, New York City.

Post-Operative Phlebitis, J. G. Clark, Philadelphia.

Conservative Operation Upon the Ovary, L. H. Dunning, Indianapolis.

Hematoma of the Ovary, A. L. Beahan, Canandaigua, N. Y.

Ten Years in a Gynecologic Clinic, David J. Doherty, Chicago.

Surgical Treatment of Internal Hemorrhoids from the Standpoint of the Gynecologist, Wm. F. Metcalf, Detroit, Mich.

#### Section on Surgery and Anatomy.

Chairman, DeForest Willard, Philadelphia; Secretary, James B. Bullitt, Louisville.

Chairman's Address.

The Surgical Treatment of Pulmonary Abscess Following Lobar-Pneumonia, Floyd W. McRae, Atlanta, Ga.

A Contribution to the Surgery of the Lung as Based Upon Original Observations, Horace J. Whitacre, Cincinnati.

Climate as a Factor in the Management of Genito-Urinary Tuberculosis, Chas. A. Powers, Denver.

Tubercular Peritonitis: Its Relation to Tuberculosis of the Female Genitalia, John B. Murphy, Chicago.

Two Cases of Tubercular Peritonitis in Young Women; Free Incision, Drainage, Enclosure of Oxygen in the Abdominal Cavity by Hermetical Sealing of the Wound, Maurice H. Richardson, Boston.

Report of a Case of Encysted Dropsy of the Peritoneum, Tubercular in Character, with Hernia of a Portion of the Cyst; Operation: Recovery. Light as a Curative Agent in Tubercular Peritonitis, Miles F. Porter, Fort Wayne, Ind.

Low Lateral Pharyngotomy for Approach to the Lower Portion of the Pharynx, Upper Portion of the Esophagus and Posterior Surface of the Larynx, with an Illustrative Case, Joseph D. Bryant, New York City.

Further Experiences with a Modified Method for the Cure of Relapsing Talipes Equino-Varus, A. F. Jonas, Omaha, Neb.

The Treatment of Acetabular Disease of the Hip-Joint, E. H. Bradford, Boston.

The Prevention of Deformity, Wisner R. Townsend, New York City.

The Value of Manual Training in Mechanics to the Surgical Student, S. D. Van Meter, Denver.

Gunshot Wounds of Cavities: Civil Side, Wm. L. Rodman, Philadelphia.

Gunshot Injuries of the Chest and Abdomen, from the Military Standpoint, L. LaGarde, Washington, D. C.

Gunshot Wounds of the Large Joints, J. D. Griffith, Kansas City, Mo.

Treatment of Gunshot Wounds of Large Joints: Military Practice, George Ryerson Fowler, Brooklyn.

A Contribution to Surgery of the Pancreas, C. H. Frazier, Philadelphia.

The Surgical Aspects of Acute Pancreatitis and Fat Necrosis, William J. Mayo, Rochester, Minn.

Surgery of the Gall-Bladder and Bile Ducts, Alexander Hugh Ferguson, Chicago.

Why Not Treat the Gall-Bladder as We Do the Appendix Vermiformis? Roswell Park, Buffalo, N. Y.

Gallstones in the Common Duct, Martin B. Tinker, Baltimore.

Appendicitis; a Critical Review of 416 Cases Operated on at the German Hospital During 1901, John B. Deaver and Geo. G. Ross, Philadelphia.

Appendicitis; a Brief Report of the Author's Nine Fatal Cases, with Comments, Parker Syme, New York City.

Some Anomalies in Appendicitis, Ernest Laplace, Philadelphia.

Obstructions of the Bowels by Meckel's Diverticulum, James E. Moore, Minneapolis.

Prostatic Obstructions to Urination; Indications for Operative Procedures for Its Removal, J. W. S. Gouley, New York City.

Infra-Pubic Section for Prostatotomy and Prostatectomy, E. Wyllys Andrews, Chicago.

Drainage of Extra-Vesical and Extra-Peritoneal Suppurations of the Male Pelvis, Eugene Fuller, New York City.

External Urethrotomy from the Standpoint of the General Surgeon, John C. Munro, Boston.

The Symptomatology of Renal and Ureteral Disease, C. L. Leonard, Philadelphia.

Essentials in the Construction of Hospitals for Great Cities, A. J. Ochsner, Chicago.

Shook, Edward Martin, Philadelphia.

Anatomy for the Practitioner, C. M. Jackson, Columbia, Mo.

Treatment of Fractures of the Neck of Femur, C. E. Thomson, Scranton, Pa.

Anatomic Treatment of Fractures of the Femoral Neck, C. E. Ruth, Keokuk, Ia.

Ununited Fractures, S. H. Weeks, Portland, Me.

Simple Periosteal-capsular Approximation with Buried Sutures vs. Wiring or Osseous Suture in Treatment of Fractured Patella, with Report of Cases, Rudolph Matas, New Orleans.

Treatment of Fracture of the Patella by Subcutaneous Purse-String Suture, John B. Roberts, Philadelphia.

Acquired Non-Malignant Stricture of Rectum; Causes, Symptoms, and Treatment, W. Duff Bullard, New York City.

Removal of the Entire Scapula, Edwin Field, Red Bank, N. J.

Surgery of the Heart (Experimental), with Stereopticon Illustrations, B. M. Ricketts, Cincinnati.

Fractures of the Lower End of the Radius, Illustrated by Lantern Slides, Carl Beck, New York City.

Traumatic Rupture of the Abdominal Viscera, Daniel N. Eisendrath, Chicago.

The Remote Results of the Non-Surgical Treatment of Peritonitis, H. D. Niles, Salt Lake City.

Some Clinical Observations in Intestinal Surgery, A. Morgan Vance, Louisville, Ky.

A Study of the Relative Merits of the Various Methods of Intestinal Anastomosis, R. C. Coffey, Portland, Ore.

The Improvement of General Anesthesia on Basis of Schleich's Principles, with Special Reference to Anesthol, Willy Meyer, New York City.

One Thousand Personally Conducted Cases of Ethyl Chlorid Narcosis, Martin W. Ware, New York City.

Medullary Narcosis, A. W. Morton, San Francisco.

A Contribution to Ureteral Surgery, with Report of a New Operation for the Cure of a Double Uretero-Vaginal Fistula, N. O. Werder, Pittsburg, Pa.

### Section on State Medicine (Hygiene and Sanitary Science).

Chairman, Arthur R. Reynolds, Chicago; Secretary, H. M. Bracken, Minneapolis, Minn.

#### TUBERCULOSIS.

Relation of Bovine to Human Tuberculosis, papers by D. E. Salmon, U. S. Bureau of Animal Industry, Washington, D. C., and R. R. Dinwiddie, U. S. Agricultural Experiment Station, Fayetteville, Ark.

Sanitarium Treatment of Tuberculosis, S. C. Bonney, Denver.

The U. S. Sanitarium and Hospital for the Treatment of Pulmonary Tuberculosis, D. M. Appel, Ft. Bayard, N. M.

State and Municipal Sanitaria—the Present Aspect of the Tuberculosis Problem in the United States, S. A. Knopf, New York City.

Sanitarium Treatment for Tuberculosis, Based on the Experience at Fort Stanton, P. M. Carrington, Ft. Stanton, N. M.

Climatic Treatment of Tuberculosis, David R. Fly, Amarillo, Texas.

Treatment of Pulmonary Tuberculosis from the Sanitarium Standpoint, J. Evans Stubbett, Liberty, N. Y.

The Care of the Skin in Pulmonary Tuberculosis, J. Frank McConnell, Las Cruces, N. M.

Individual and Municipal Prophylaxis of Tuberculosis, Arnold C. Klebs, Chicago.

Sanitary Measures for the Prevention of Tuberculosis in New York City and Their Results, Herman M. Biggs, New York City.

Are Milk and Meat Sources of Seed Supply for Human Tuberculosis? Lawrence F. Flick, Philadelphia.

#### VACCINATION AND SMALLPOX.

Some Facts About Vaccination, Heman Spalding, Chicago.

Laboratory Inspection of Vaccine, Adolph Gehrmann, Chicago.

#### INFLUENZA.

The Sociologic Relations of Influenza, James G. Kiernan, Chicago.

A Further Contribution to the Bacteriology of Influenza, F. E. Wynekoop, Chicago.

Influenza and the Nervous System, Smith Ely Jelliffe, New York.

#### PNEUMONIA.

Pneumonia—Its Increasing Prevalence and Fatality, with Suggestions for Individual and Communal Prophylaxis, Edward F. Wells, Chicago.

Epidemicity and Increasing Fatality of Pneumonia, James J. Walsh, New York.

#### MISCELLANEOUS.

The Use of the Microscope in the Diagnosis of Scarlet Fever, W. K. Jaques, Chicago.

Sanitation and Politics, Walter Wyman, Washington, D. C.

The Drainage Canal of the Valley of Mexico, Henry O. Marcy, Boston.

Among those to discuss the foregoing are: William Osler, Johns Hopkins; Benjamin Lee, Pennsylvania; Victor C. Vaughan, Michigan; A. C. Cotton, Illinois; William M. Welch, Pennsylvania; W. A. Evans, Illinois; Mazyek P. Ravenel, Pennsylvania; George Doek, Michigan; Wyatt Johnston, Canada; E. S. St. B. Sladen, Cambridge, Eng., and others.

### Section on Ophthalmology.

Chairman, Frank Allport, Chicago; Secretary, C. A. Veasey, Philadelphia.

Address of the Chairman, Frank Allport, Chicago.

Blepharitis Marginalis, Dudley S. Reynolds, Louisville, Ky.

Sub-Conjunctival Inflammations, Henry Gradle, Chicago.

The Treatment of Serpiginous Ulcer of the Cornea, Chas. J. Kipp, Newark, N. J.

The Nature and Treatment of Pterygia, John O. McReynolds, Dallas, Texas.

Triosinamin in Corneal Opacities; Experiences and Clinical Results, Geo. F. Suker, Chicago.

Address: The Removal of Foreign Bodies from the Eye, Prof. O. Haab, Zurich, Switzerland.

Foreign Bodies in the Eye, Wm. M. Sweet, Philadelphia.

A Report of Some Cases of Foreign Bodies in the Eye; Where Haab's Magnet Was Used, Myles Standish, Boston.

An Operation for the Restoration of a Cul-de-Sac for the Wearing of an Artificial Eye, with Report of Cases, John E. Weeks, New York City.

The Relative Indications for Enucleation and the Mules Operation, N. J. Hepburn, New York City.

On the Symmetry of Our Visual Apparatus as a Dual Organ. Plea to Modify the Customary Notation of the Ocular Meridians, Herman Knapp, New York City.

Concerning the Symptomatology and Etiology of Certain Types of Uveitis, Geo. E. de Schweinitz, Philadelphia.

An Analysis of Thirty-seven Cases of Uveitis, with Special Reference to, 1, Etiology; 2, Relapses; 3, Rare Early Symptoms and Ophthalmoscopic Changes; 4, Importance of Perimetric Examinations, Hiram Woods, Baltimore.

The Diagnostic Significance of Keratitis Punctata, Harry Friedenwald, Baltimore.

Injuries of the Eye Productive of Diseases of the Uveal Tract, Howard F. Hansell, Philadelphia.

The Pathology of Uveitis, W. H. Wilder, Chicago.

Pilocarpin Injections in Diseases of the Uveal Tract, T. A. Woodruff, Chicago.

The Treatment of Uveitis, W. B. Marple, New York City.

Exhibit of Early American, British and Colonial Ophthalmologic Literature, by a Committee Consisting of Dr. Casey A. Wood, Chicago, Chairman; Dr. A. R. Baker, Cleveland, Ohio; Dr. A. A. Hubbell, Buffalo; and Dr. Harry Friedenwald, Baltimore. Address by the Chairman of the Committee.

Neuro-Epithelioma Retinae (Glioma), with Report of Cases; Illustrated, C. R. Holmes, Cincinnati.

Detachment of the Retina, R. L. Randolph, Baltimore.

The Most Rational Methods of Asepsis in Ophthalmic Surgery, Joseph A. White, Richmond, Va.

Cataract Extractions, with Remarks, David Webster, New York City.

The Disappearance of Opacities of the Crystalline Lens, Walter Pyle, Philadelphia.

The Anatomy of the Ocular Muscles and Their Accessory Structures, J. Elliott Colburn, Chicago.

The Physiology of the Ocular Muscles, with Demonstrations, E. C. Ellett, Memphis, Tenn.

Principles Controlling Operative Interference in Heterophoria, E. J. Gardiner, Chicago.

Principles Controlling Non-Operative Interference in Heterophoria, Including the Use of Prisms and Prism Exercise, S. C. Ayres, Cincinnati.

Dento-Facial Orthopedia, W. E. Walker, New Orleans.

#### Section on Nervous and Mental Diseases.

Chairman, Richard Dewey, Wauwatosa, Wis.; Secretary, F. Savary Pearce, Philadelphia.

Address of Chairman, Richard Dewey, Wauwatosa, Wis.

Memorial to Dr. J. T. Eskridge, Charles K. Mills and Frank P. Norbury.

After-Results in Some Cases of Alleged Trauma to the Nervous System, Haldor Sneve, St. Paul, Minn.

Educational Exercise in Locomotor Ataxia, J. H. W. Rhein, Philadelphia.

Symmetrical Gangrene (Raynaud) Versus Endarteritis Obliterans, Jas. D. Morgan, Washington, D. C.

Prognosis of Mental Diseases, Frank P. Norbury, Jacksonville, Ill.

Alcoholic Epilepsy, T. D. Crothers, Hartford, Conn.

The Babinski Phenomenon in Insane Epileptics (Results of a Thousand Observations), J. M. Keniston, Middletown, Conn.

Exceptional Forms of Pressure Palsies, J. D. McCarthy, Philadelphia.

Concerning Morphin Addiction and Its Treatment, C. B. Burr, Flint, Mich.

Static Electricity in the Treatment of Morphinism, A. J. Pressey, Cleveland, Ohio.

The Diagnostic Value of Lumbar Puncture in Certain Cases of Brain Injury (Report of Cases), G. W. McCaskey, Fort Wayne, Ind.

Peripheral Neuritis as a Complication of Whooping Cough, A. A. Eshner, Philadelphia.

A Résumé of Pathologic Findings in Fifty-one Cases of Insanity, E. G. Carpenter, Columbus, Ohio.

Huntington's Chorea, Harold N. Moyer, Chicago.

Some Conditions with Which Migraine May be Associated; Their Value as an Indication for Treatment, Joseph Sailer, Philadelphia.

Paretic or Paranoiac—A Study in Diagnosis, C. A. Drew, Bridgewater, Mass.

Cases Illustrating Involuntary Movements in Ataxia, J. H. W. Rhein, Philadelphia.

Dementia Paralytica in Children, Sydney Kuh, Chicago.

Locomotor Ataxia Complicated by Thrombosis of the Pontine Arteries, etc., S. D. Hopkins, Denver, Colo.

Encephalic Localization, Especially with Reference to Osteoplastic Operations for Brain Tumors, Charles K. Mills, Philadelphia.

The General Principles of Symptoms in Nervous Diseases, Herman Gasser, Platteville, Wis.

Intoxication Insanities, W. A. Jones, Minneapolis.

SYMPOSIUM ON EPILEPSY (SECOND DAY—AFTERNOON).

Etiology and Pathogenesis of Epilepsy, F. Savary Pearce, Philadelphia.

Diagnosis, Symptomatology, Anomalous Forms, Relation to Hysteria, Migraine, Etc., C. W. Burr, Philadelphia.

Psychopathology and Medicolegal Relations. H. A. Tomlinson, St. Peter, Minn.

Treatment, Medicinal, Hygienic and Surgical, D. R. Brower, Chicago.

Institutions for the Epileptic, Wm. P. Spratling, Sonyea, N. Y.

Discussions to be opened as follows:

(a) Etiology, Etc.: F. W. Langdon, Cincinnati.

(b) Diagnosis, Etc.: H. N. Moyer, Chicago.

(c) Psychopathology, Etc.: A. B. Richardson, Washington, D. C.

(d) Treatment: F. Savary Pearce, Philadelphia.

(e) Institutions: Frederick Peterson, New York City.

N. B.—Papers are limited to 20 minutes. Discussions are limited to 5 minutes. Abstracts of papers should be sent to the Secretary at once. Those members of the Association intending to attend the dinner of this Section will confer a favor by writing an acceptance that we may know early for how many to provide.

#### Section on Cutaneous Medicine and Surgery.

Chairman, Henry W. Stelwagon, Philadelphia; Secretary, R. R. Campbell, Chicago.

Chairman's Address, Henry W. Stelwagon, Philadelphia.

Syphilis as a Causative Factor of Pyorrhea Alveolaris, A. H. Ohmann Dumesnil, St. Louis.

Pathology of Chromidrosis, with Lantern Slide Demonstration, M. L. Heidingsfeld, Cincinnati.

Exhibition of Wax Models of Unusual Types of Skin Diseases, J. Frank Wallis, Philadelphia.

Dermatitis Repens, Milton B. Hartzell, Philadelphia.

Report of Four Cases of Syphilis Mistaken for Smallpox, with Differential Diagnosis, J. F. Schamberg, Philadelphia.

Dermatitis Hiemalis, William Thomas Corlett, Cleveland.

Atrophoderma, with Report of Two Cases, A. Ravogli, Cincinnati.

Rest in Skin Diseases, R. Abrahams, New York.

Report of a Case of Recurrent Bullous Eruption and Sarcoma of the Skin; a Study of Five Cases, W. S. Gottheil, New York.

Pityriasis Rosea, L. Weiss, New York.

Parasitic Fungoid Diseases, Jay F. Schamberg, Philadelphia.

Venereal Prophylaxis that Is Feasible, Ludwig Weiss, New York.

Sarcomatosis Cutis, David Lieberthal, Chicago.

The Relation of Lupus Erythematosus to Tuberculosis, Henry G. Anthony, Chicago.

A Contribution to the Subject of Radiotherapy and Phototherapy in Carcinoma, Tuberculosis and Other Diseases of the Skin, James Nevins Hyde, Frank Hugh Montgomery and Oliver S. Ormsby, Chicago.

Etiology of Psoriasis, William L. Baum, Chicago.

Treatment of Skin Diseases By Means of the X-Rays, Louis E. Schmidt, Chicago.

Syphilis of the Larynx, C. M. Robertson, Chicago.

Glanders in Man, L. Blake Baldwin, Chicago.

#### Section on Laryngology and Otology.

Chairman, G. Hudson Makuen, Philadelphia; Secretary, J. F. Barnhill, Indianapolis.

Address of Chairman, G. Hudson Makuen, Philadelphia.

Some Practical Suggestions Concerning the Use of Tuning Forks in the Diagnosis of Ear Diseases, Wm. L. Ballenger, Chicago.

The Early Appearance, Diagnosis and Treatment of Tuberculosis of the Upper Air Tract, Walter F. Chappell, New York City.

Transillumination of the Accessory Sinuses During Acute Coryza, C. M. Cobb, Lynn, Mass.

A Case of Severe Syphilitic Laryngitis Complicated by Pulmonary Involvement, P. S. Dornellan, Philadelphia.

The Diagnosis of Carcinoma of the Larynx, O. T. Freer, Chicago.

An Unusual Case of Sero-Sanguinous Exudation from Both Ears, M. A. Goldstein, St. Louis.

A Case of Sarcoma of the Maxillary Sinus, Partial Excision of the Upper Jaw and Remarks, Joseph S. Gibb, Philadelphia.

Rhinitis Caseosa, A. C. Getchell, Worcester, Mass.

Development of the Organ of Hearing; Illustrations, C. R. Holmes, Cincinnati.

Turbinotomy; Its Indications and Technic, Chevalier Jackson, Pittsburg, Pa.

A Case of Laryngectomy, E. Fletcher Ingals, Chicago.

Oleum Pinus Pumilionis as a Valuable Aid in Lessening the Irritating Effects of Anesthetics, D. Braden Kyle, Philadelphia.

A Case of Brain Abscess, Geo. F. Keiper, LaFayette, Ind.

Nerve Nostrums and Their Dangers, William P. Spratling, Sonyea, N. Y.

Hypnotics, Analgesics and Resultant Drug Addictions, Smith Ely Jelliffe, New York City.

Dosage of Liquid Medicines: A Simple Plan for Greater Accuracy and Metric Measures, Carl S. N. Hallberg, Chicago.

#### Section on Physiology and Pathology.

Chairman, Frank B. Wynn, Indianapolis; Secretary, Joseph McFarland, Philadelphia.

The Pathology of Asthma, with Special Reference to Its Vicious Circles, George N. Jack, Depew, N. Y.

Skin Lesions of Smallpox, J. F. Schamberg, Philadelphia.

Some Comparative Studies in Tuberculosis, E. A. de Schweinitz, Washington, D. C.

The Histologic Changes in the Tissues in Banti's Disease, Joseph Sailer, Philadelphia.

Present Status of the Blood Plates in Physiology and Pathology, George T. Kemp, Champaign, Ill.

A Case of Perforation of the Normal Intestine by an Ascaris Lumbricoides; Specimen; Literature, Louis C. Ager, Bay Ridge, N. Y.

Ankylostomiasis in the South. Report of Cases and Presentation of Specimens, Claude A. Smith, Atlanta, Ga.

The Clinical Application of the Thyroid Gland, L. Breisacher, Detroit, Mich.

Recent Investigations of the Mechanics of Digestion, W. B. Cannon, Boston.

The Chest-Pantograph: Its Physiologic Significance and Its Clinical Application, Winfield S. Hall, Chicago.

A Demonstration of the Movements of the Stomach and Intestines, W. B. Cannon, Harvard, Boston.

The Laboratory Method of Teaching the Medical Sciences, Accompanied by Exhibit of Some New Physiologic Apparatus, W. T. Porter, Boston.

Exhibit of Some New Physiologic Apparatus, W. T. Porter, Boston.

The Influence of Tuberculosis Upon the Respiratory Quotient, T. M. Alderhold, Chicago.

Identity of Nerve Force and Electricity, J. Emmet O'Brien, Scranton, Pa.

On Some Rare Forms of Chronic Peritonitis Associated with Productive Fibrosis and Hyalin Degeneration, A. G. Nicholls, Montreal, P. Q.

Post-Mortem Examinations, W. D. Haines, Cincinnati.

Discussion: The Best Methods of Teaching Pathology, Ludvig Hektoen, Chicago; F. F. Westbrook, Minneapolis; Frank B. Wynn, Indianapolis; Joseph McFarland, Philadelphia.

Paper (promised), Alfred Stengel, Philadelphia.

Paper (promised) F. F. Westbrook, Minneapolis.

The Clinical and Pathologic Aspects of Rabies, D. J. McCarthy and M. P. Ravenel, Philadelphia.

A Case of Typhoid and Meningitis with Pseudo-Diphtheria Bacillus in the Brain, A. P. Ohlmacher, Chicago.

Points Relative to Precipitins, W. A. Evans and Adolph Gehrmann, Chicago.

Observations on the Absorption of Albumins and Globulins, Charles T. McClintock, Detroit, Mich.

Bacterial Poisons, Victor C. Vaughan, Ann Arbor, Mich.

A Note on the Chemical Diagnosis of Hypernephroma of the Kidney, A. O. J. Kelly and A. C. Croftan, Philadelphia.

Case of Endothelioma of Pleura, W. E. Robertson, Philadelphia.

#### SYMPOSIUM UPON CARCINOMA.

On Lepidomata and Hylomata, George Adami, Montreal.

Cell Implantation in the Production of Tumors, Leo Loeb, Chicago.

A Contribution to the Study of the Production of Endothelioma of the Dura and Brain, D. J. McCarthy, Philadelphia.

Endothelioma of the Gall-Bladder, W. Becker, Milwaukee, Wis.

The Growth of the Tubercle Bacillus and Other Organisms Resembling the Tubercle Bacillus upon Fruits and Vegetables, M. J. Rosenau, Washington, D. C.

Clinical Methods of Determining Blood-Pressure, Joseph Erlanger, Baltimore.

# THE SARATOGA SPRINGS MEETING

## SITUATION.

Saratoga Springs has become the favorite convention town of the United States for national organizations of every kind. It owes this distinction partly to its natural advantages and partly to its unequaled—indeed, we might say, its unapproached—facilities for the entertainment of such gatherings. Nature has made it the great

## HOW TO REACH SARATOGA.

Saratoga Springs is readily accessible from the south and west by the lines of the Vanderbilt system, the New York Central and the West Shore and Boston & Albany roads, bringing their passengers to Albany and Schenectady, from which points the Delaware & Hudson have but a short run to the Spa. From the north,

PART OF REGISTRATION ROOM.

health resort of this continent and one that is not surpassed in its comforts and attractions anywhere in the world. Situated on a plateau at the end of the foothills of the Adirondacks, a region deservedly famed for its salubrity, it has an elevation of three hundred and twelve feet above tide water level and is swept by the breezes of the great northern forests. The celebrity of Saratoga is, however, largely owing to its natural mineral waters.

the Delaware and Hudson gives connection with the Canadian lines and with several New England systems. By the Boston & Maine, Massachusetts and other parts of New England find easy access directly to the village. The fine river steamers plying on the Hudson, both by day and by night, afford a charming trip to those who choose to travel by water. Arrangements for reduced rates have not been perfected as yet, but it is absolutely assured that a concession of a fare

and a third will be given, with the possibility that a further reduction in the rate may be granted.

#### MINERAL SPRINGS.

The mineral springs of Saratoga have a world-wide fame. There are more than forty of them and they are not more remarkable for their number than they are for their variety. They embrace many kinds of mineral waters, saline, alkaline, chalybeate, sulphur, lithia, etc.,

WINDSOR HOTEL.

with a wide range of both hygienic and therapeutic action. It will be an additional matter of interest to the members of the convention to have the opportunity to familiarize themselves with these marvelous fountains of health and become acquainted with the special virtues of each one of them.

WORDEN HOTEL.

#### HOTELS.

There are no summer resort hotels anywhere that can be compared with the caravansaries of Saratoga. They are not the frail combustible structures one generally associates with the idea of the accommodations at a watering place, most of them and all the larger ones being solid, practically fire-proof buildings of brick, stone and iron. Some of them cover all, or practically all of a block, with courtyards which are really parks

of several acres, with forest trees, fountains and flowers, broad walks and large greenswards, which are as unique as they are beautiful. Some of these great hostelries often accommodate as many as two thousand guests at the same time. One of these, the United States, will be the headquarters of the Association, where a band of music will give open air concerts morning and evening and where a grand reception and ball will be given on

KENSINGTON HOTEL.

Wednesday evening of the convention week. There are, in addition to these large hotels, more than 150 smaller hotels and boarding houses, accommodating comfortably over 10,000 guests.

Saratoga Springs is so compactly built that most of these houses are in the vicinity of Convention Hall,

ADOLPHUS-AMERICAN.

where the general sessions will be held, and none of them is more than three minutes walk away. This is a matter of great importance, facilitating the interchange of friendly visits, and promoting that social intercourse which is one of the most charming features of such a gathering.

Below we give a list of the important hotels of Saratoga Springs, with prices. Besides those mentioned there are a number of boarding houses whose rates vary

from \$1 to \$2 per day. The chairman of the committee on hotels is Dr. J. R. Swanick, Saratoga Springs, who will be glad to engage rooms in advance for those who will write to him:

| Hotels.                     | Accommodations. | Single rooms. | Single rooms, with bath. | Double rooms. | Double rooms, with bath. |
|-----------------------------|-----------------|---------------|--------------------------|---------------|--------------------------|
| Grand Union . . . . .       | 1500            | \$4 00 up     | \$6 00 up                | \$8 00 up     | \$10 00 up               |
| United States . . . . .     | 1200            | 4 00-5.00     | 6 00-7.00                | 8 00-10 00    | 10 00-12 00              |
| American-Adelphi . . . . .  | 300             | 3 00-4.00     | 4.00-5.00                | 6 00-8 00     | 8 00-10.00               |
| Kensington . . . . .        | 500             | 3 00-4.00     | 4.00-5.00                | 6.00-7 00     | 8.00-10 00               |
| Columbian Hotel . . . . .   | 250             | 3.00          | 4.00                     | 5 00          |                          |
| Warden Hotel . . . . .      | 250             | 3.10          | 4.00                     | 6 00          |                          |

#### PARKS AND PLEASURE GROUNDS.

Saratoga is itself a splendid park, with broad shaded avenues, with hundreds of elegant villas and spacious

GRAND UNION HOTEL, BROADWAY FACADE.

mansions to delight the eye of the visitor. But there are special grounds set apart for the enjoyment of guests. One of these, the Congress Spring Park, almost immediately joins the Convention Hall. It is ten or fifteen acres in extent, with handsome spring pavilion and a long colonnade, a miniature lake over which a music stand is built and where a band concert will be given on Wednesday morning. The grounds are diversified with hill and dale, there is a trout pond and deer paddock; altogether it is said to be the finest park of its size in the world. Adjoining the village limits on the north is the famous Woodlawn Park, the country seat of the late Judge Henry Hilton of New York. These magnificent grounds, open to the public, comprise over two thousand acres, with lake, forest, fine villas, and over twenty miles of smooth solid roadways. The views through vistas are wonderful in their sweep. To the east one can see the Green Mountains; to the south the Catskills are visible, and to the west are the lovely and picturesque Kaya-

derosseras Hills, a spur of the Adirondacks. East of the village, a drive of one mile from the Convention Hall brings one to the Saratoga Racing Park, upon which more than \$250,000 has been expended since last summer, making it the most splendid racing park in either Europe or America. It can be visited by carriage or, if one prefers, on foot, as there is a paved sidewalk extending all the way to the entrance gates. Immediately east of the park lie the magnificent grounds of

CONVENTION HALL.

"Yaddo," the country home of Mr. Spencer Trask, the New York Banker. These grounds are open also to carriages or pedestrians. The great stone mansion, with its lofty and spacious terrace and the finest rose garden in America will be found of surpassing interest.

TOWN HALL.

#### OTHER ATTRACTIONS IN THE VICINITY.

Extending east and west, a couple of blocks north of the racing park, is the recently completed speedway. It is an extension of one of the village streets, over a mile in length, with a roadway for speeding sixty feet wide and a carriage drive thirty feet wide on either side, separated from the speedway proper by strips of lawn, set out with forest trees. Four miles east is Saratoga Lake, reached by a wide avenue and also by a trolley

line. This is a lovely sheet of water, with picturesque shores, on which are many hotels famed for their fish and game dinners. Saratoga Lake has been the scene of many regattas, including those of the Intercollegiate Rowing Association, where no less than fourteen crews once contested for supremacy. The lake is supplied with steam launches, which may be chartered by excursion parties, some of them also making regular trips through the lake, which is nine miles long and three

INTERIOR OF CONVENTION HALL.

miles wide at the widest part. It is a great fishing ground and rowboats may also be secured with fishing outfits for those fond of piscatorial sport. South of the village, one mile away, is the remarkable group of gey-

UNITED STATES HOTEL. HEADQUARTERS.

sers, or spouting springs, which may be visited by carriage or trolley. Just to the west of the village and reached by a fine drive are the beautiful grounds of the Saratoga Golf Club, by many said to be, for their extent, the most perfect links in the United States. The club is always glad to extend its courtesies to transient guests and to those who remain for any length of time it extends the privilege of temporary membership under proper restrictions.

Close to the golf links and a little to the north, the Saratoga Polo Association has its beautiful grounds. Although this association is not old in years, it has already achieved distinction in the polo world and under its direction this year, from July 28 to August 9, there will be held the championship contests of the country.

#### EXCURSIONS.

Saratoga offers many delightful excursions. To the north, six miles distant, is Mt. McGregor, on whose sum-

CONGRESS HALL.

mit Gen. U. S. Grant spent the closing days of his life. The cottage in which he died is in charge of a government custodian and is kept unchanged, as it was while Gen. Grant occupied it. It is open to visitors and is accessible by a good carriage road. On the western side of the mountain, along which the Hudson River flows,

IN "YABDO."

is the great dam across this historic stream. From this waterpower, electric machines are to be operated for supplying the motive force for manufacturing establishments within a radius of fifty miles.

Some thirty miles to the north lies Lake George, renowned for its grand scenery and historic associations. This may be reached by steam or trolley railroad. An excursion to Lake George will be made during the convention.

Luzerne, a thriving village with falls in the Upper Hudson and a remarkably pretty lake, is only one hour away by the Adirondack railroad. East of Saratoga, a half hour by rail, is Schuylerville, where a noble battle monument overlooks the scene of Burgoyne's surrender, and the Burgoyne battlefield near by. The points where the decisive struggle for American Independence was made are plainly marked by tablets suitably inscribed.

Among the excursions contemplated from Saratoga Springs following the meeting is a nine days' trip, starting June 13, through Lake George and Lake Champlain,

#### IN SARATOGA SPRINGS.

There are many interesting features in the village itself. Among these is the Pompeia, adjoining the Convention Hall. This is an exact reproduction of the "House of Pansa." The rooms, furniture, decorations, statues, etc., are of exceeding interest. The hotels and the many mineral springs will be found filled with interest. The Saratoga Baths, one of the finest bath houses in the United States, will be found exceedingly interesting to all members of the convention. Saratoga's fine water supply and modern system of sewage disposal are well worthy of attention.

ON THE LINKS.

passing historic "Fort Ti," reaching Burlington, the "Queen City" of Vermont, and taking an electric car ride to the U. S. Army Post; then to Montreal, Saturday morning visiting the famous Lachine Rapids and the sights of the city, and Sunday p. m., a sail down the St. Lawrence to Quebec. Monday evening the party will go by special train to the White Mountains and stop there until Wednesday, when the party will journey past many points of interest to Poland Springs, stopping there on invitation of the proprietors; thence to Boston, where a reception will be tendered and a carriage drive about the city given. Further information in regard to this trip can be obtained by addressing Dr. Edward R. Campbell, Bellows Falls, Vt.

#### MEETING PLACES.

The feature of the Saratoga meeting which will unquestionably meet with the favorable consideration of those who are in attendance and will redound to the credit of Saratoga as a convention city will be found in the close proximity of the various places of meeting. Three minutes' walk is the outside time measurement required to walk between the most remote sections. The places of meeting are as follows:

General Sessions, Convention Hall, Broadway.

Post-office, General Exhibits, Bureau of Registration, Bureau of Information, Hathorn Spring Building, Spring St.

Practice of Medicine, Grand Union Parlors.

Pathologic Exhibits, Congress Hall ballroom. Broadway and Spring St.

Obstetrics and Diseases of Women, Theater Saratoga, Philadelphia St., just east of Broadway.

Surgey and Anatomy, Patterson Spring Building, Philadelphia St., opposite Theater.

Hygiene and Sanitary Science, United States Hotel, Broadway and Division St.

Ophthalmology, Laryngology and Otology, Y. M. C. A. Building, Broadway, opposite Caroline St.

Diseases of Children, Parish House, 17 Washington St.  
Stomatology, G. A. R. Hall, Post-office Building, opposite U. S. Hotel.

Nervous and Mental Diseases, Grand Union Hotel.

Cutaneous Medicine and Surgery, American Hotel, Broadway, opposite Philadelphia St.

Materia Medica, Pharmacy and Therapeutics, Grand Union Hotel.

House of Delegates, Supreme Court Room, Town Hall.

Trustees, Judicial Council, United States Hotel.

The Convention Hall, where the general meetings will be held, is in the heart of the village. It is one of the largest and best-equipped places for great assemblages in the United States. It has seats for five thousand people, with stage, telegraph facilities, committee rooms and everything else required for the speedy and successful dispatch of business.

The General Exhibit will be displayed in the Hathorn Springs Building, an immense room on the ground floor, within a block of Convention Hall. Under the same roof will be found the Post-office, Telegraph Office and the Bureaus of Information and Registration. The various sections will hold their sessions in hotel parlors and halls, in close proximity to each other.

#### SCHEDULE OF ENTERTAINMENT.

The entertainments include the following:

Tuesday evening, June 10, Piazza Concert at the United States Hotel. Mr. Thomas Impett, the celebrated Troy tenor and a quartette will sing a number of selections.

Wednesday morning, Concert in Congress Spring Park.

Wednesday afternoon, carriage drive about village and reception at "Yaddo."

Wednesday evening, Reception and Ball at United States Hotel. The large interior court of the hotel will be brilliantly illuminated with colored lanterns, as though prepared for a garden party.

Thursday morning, June 12, Excursion to Lake George for the ladies.

Thursday evening, President's Reception at the United States Hotel.

To fully appreciate the unique interest of these entertainments and excursions, the reader should notice the descriptions of Congress Spring Park, Yaddo, Lake George, etc., in preceding paragraphs of this article.

The Committee of Arrangements for this meeting has been fortunate in having the warm support of the Saratoga Business Men's Association and of the community at large in its efforts to make adequate preparation for the coming of the American Medical Association.

Under the direction of the officers of the A. M. A. great care has been exercised in making the plans for the entertainment of our guests. It was early impressed upon the committee that the scientific work of the meeting must have first place and that nothing should be permitted to interfere with this, the primary object of the meeting. For this reason, certain features which have appeared on the programs of entertainment heretofore, have been eliminated this year and, so far as the Committee has received information from members of the Association, this action has been most heartily commended. It need not be feared from the foregoing explanation, however, that there will be any lack of the elements which go to make up the social features which add so greatly to the pleasure of the annual gatherings.

Any special or further information will be promptly and cheerfully supplied by addressing

DR. GEO. F. COMSTOCK,  
*Chairman, Committee of Arrangements.*

---

**Precautions Necessary with Hydrogen Dioxid.**—Two professors at Lyons, France, have recently called attention to the ready absorbability of hydrogen dioxid and the consequent danger of fatal gaseous embolism from bubbles of oxygen forming in the blood after absorption, when it is applied to an open wound or to detach an adherent dressing. In contact with the blood, as with pus, the effervescence continues. The oxygen is disposed of by the oxyhemoglobin in the blood if the amount is small, and no harm results. Inflamed tissues are peculiarly active in decomposing the dioxid, and absorption is always slow and gradual in all cases. Crolas advises rendering the dioxid alkaline by adding a saturated solution of sodium borate, a drop at a time, until litmus paper, first reddened by the dioxid, regains its blue color. Even aside from the fear of gaseous embolism the dioxid should always be neutralized, as it is liable to contain more or less sulphuric, phosphoric, or other acids. It should never be used stronger than eight to ten volumes, and always fractioned and in moderate amounts. With these precautions there need be no fear of the slightest evil effects from its use.—*Pacific Medical Journal.*

**Alcohol Corrodes.**—Physicians who have read that absolute alcohol is used at Johns Hopkins Hospital for sterilizing and those who have found that its use is corroding will be interested in a statement from *Science*. The action of alcohol on metal is peculiar. Dr. Malmjac in his experiments used 95 per cent. alcohol, which left no residue on evaporation. The metals, copper, iron, tin, lead, zinc and galvanized iron, were corked up with alcohol in glass flasks and kept at ordinary temperatures for six months. The copper was entirely unacted upon, but in all the other flasks there was a deposit on the bottom and the metal was covered with a similar deposit. In the case of tin, lead, zinc and galvanized iron the deposit was white; that from the iron was red, resembling iron rust. All of the liquids, except that in which the lead had been placed, filtered clear; the latter retained a milky appearance after repeated filterings through double filters. The clear filtrates from iron, lead, zinc and galvanized iron gave much residue on evaporation, while the residue from tin was hardly appreciable. In the former cases it is clear that not only had the metal been oxidized, but a considerable quantity had entered into the solution. These experiments have an important bearing on the storing and shipping of alcohol.

## Married.

GUSTAV KOEHLER, M.D., to Miss Alma Lewert, both of Chicago, April 24.

JAMES J. MOONEY, M.D., to Miss May Cronyn, both of Buffalo, N. Y., April 29.

NUMA T. WESTON, M.D., Colfax, Iowa, to Mrs. Evalyn Swan, at Jewell Junction, Iowa.

DAVID H. COOMBS, JR., M.D., to Miss Mayme Beeler, both of Charlestown, Ind., May 7.

STANLEY SMITH, M.D., Allegheny, Pa., to Miss Sophia Lavens of Bradford, Pa., April 24.

HARRISON JOSEPH TRASK, M.D., to Miss Clara Azelia Wells at St. Joseph, Mich., April 11.

JOHN E. COULTER, M.D., to Miss Fannibelle Bradley, both of De Smet, S. Dak., April 28.

JAMES T. MCGOVERN, M.D., to Miss Teresa Jene Lennon, both of Rochester, N. Y., April 21.

JOHN M. ADAMS, M.D., Ritzville, Wash., to Miss Myrtle M. Graham of Spokane, April 17.

JOHN T. COBB, M.D., Buchanan, Ga., to Mrs. Hoppie Weaver of Polk County, Ga., January 26.

LEDRA HEAZLITT, M.D., Auburn, N. Y., to Miss Norma R. Smith of Dundee, N. Y., April 23.

OTTO J. STEIN, M.D., Chicago, to Miss Evelyn Deming Daugherty of Dubuque, Iowa, April 29.

CHARLES R. HAMMAT, M.D., to Miss Hazel H. Taylor, both of Portsmouth, Ohio, at Vanceburg, Ky., April 24.

HARRY BAPTIST, M.D., Joy Depot, Albemarle County, Va., to Miss Margaret Esther Boyle of Fredericksburg, Va., April 21.

FRANK M. HERMAN, M.D., New York City, to Miss Jessie L. Stockton of Buenos Aires, Argentine Republic, at Boston, Mass., April 30.

## Deaths and Obituaries.

**Frederick A. Castle, M.D.** Bellevue Hospital Medical College, New York, 1866, a widely-known physician of New York City, died at Roosevelt Hospital in that city after an illness of six months, aged 59. Dr. Castle was a student in Bellevue when the Civil war commenced. Without waiting to take a degree, he, with a number of other young men, formed the Medical Cadet Corps, which was sent to the front as a part of the Medical Department of the Army. He later left this organization and served for two years in the navy. Toward the close of the war he returned to Bellevue, where he was graduated. He became widely known in the profession through his editorial work in connection with numerous medical journals. For a time he occupied the chair of therapeutics at Bellevue, and was later visiting physician at the Presbyterian Hospital. He was largely interested in the building of the Academy of Medicine, and was once its treasurer.

**George King, M.D.** College of Physicians and Surgeons, New York, 1847, the oldest physician of Franklin, Mass., died at his home in that place, April 25, from heart disease, after a week's illness, aged 80. For nearly three years he served in the Civil war as surgeon of the Sixteenth and the Twenty-ninth Massachusetts Volunteer Infantry. He was taken prisoner at Petersburg, Va., and confined in Libby Prison. He was a member of the Massachusetts Medical Society, the Norfolk County Medical Society and the Thurber Medical Society.

**Joseph W. Holland, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1874, prominent as a railway surgeon, ex-president of the Southwestern Iowa Medical Association, member of the International Association of Railway Surgeons and of the Iowa State Medical Society, for more than 25 years a practitioner of Osceola, Iowa, died at a hospital in Chicago, April 25, after an illness of two weeks, aged 58.

**Pembroke R. Thombs, M.D.** Rush Medical College, Chicago, 1862, a well-known physician of Pueblo, Colo., and for a number of years superintendent of the State Hospital for the Insane, died at his home in Pueblo, April 28, after an illness of two weeks, aged 62. He served as surgeon through the Civil war and at its close located in Colorado.

**William V. Hazeltine, M.D.** Long Island College Hospital, Brooklyn, N. Y., 1883, a practitioner of Warren, Pa., since 1869, one of the organizers and one-time president of the

Warren County Medical Society, and a member of the Medical Society of the State of Pennsylvania, died at his home in Warren, April 23, from pneumonia, after a short illness, aged 62.

**Charles Abner Phelps, M.D.** Harvard University, 1844, who practiced in Boston for a time, but afterward devoted his attention to politics, serving as member and speaker of the house, and senator and president of the senate, surveyor of the Port of Boston, consul at Prague, etc., died in Boston, April 27, aged 81.

**Charles H. Dougal, M.D.** University of Pennsylvania, Philadelphia, 1864, a well-known practitioner of Milton, Pa., died at his home in that place from apoplexy, April 26, aged 67. He was a medical cadet during the Civil war, and was captured and confined in Libby Prison.

**James Nott Moore, M.D.** Medical College of the State of South Carolina, Charleston, 1859, for many years a practitioner of Spartanburg, S. C., and during the Civil war a surgeon in the Confederate service, died at his residence in Columbia, S. C., April 25, aged 65.

**Jacob Deutsch, M.D.** University of Budapest, 1867, a member of the American Medical Association, Tri-State Medical Society and Tennessee State Medical Society, died at his home in Memphis, April 19, aged 62.

**Matthew H. Molloy, M.D.** M.R.C.S. England, 1867, medalist of the Carmichael School of Midwifery, Dublin, a practitioner of Roxbury for about ten years, died at his home in that place, April 23, aged 62.

**Charles Angell, M.D.** Castleton (Vt.) Medical College, 1846, who had practiced in Pittsburg, Ind., for fifty-six years, and was a veteran of the Civil war, died at his home in Pittsburg, April 18, aged 79.

**Samuel S. Wiest, M.D.** New York University, 1854, one of the oldest practitioners of Lancaster County, died at his home in Schoenck, Pa., April 27, from valvular heart disease and dropsy, aged 74.

**Alexander J. McCullough, M.D.** Western Reserve University, Cleveland, 1882, died at Spencer Hospital in Meadville, Pa., after a short illness, from congestion of the brain, April 26, aged 49.

**Calvin A. Mann, M.D.** Washington University, St. Louis, 1858, of Chester, Ill., a veteran of the Civil war and a prisoner in Libby Prison, died recently and was buried at Chester, April 19.

**Cornelius A. Johnson, M.D.** University of Michigan, 1889, division surgeon of the Grand Rapids and Indiana Railway, died at his home in Marcelona, Mich., April 28, after a long illness.

**Otis O. Whittington, M.D.** Missouri Medical College, St. Louis, 1897, of Coffeen, Ill., died at his father's home near Herrick, Ill., April 13, from hemorrhage of the lungs, aged 32.

**James Taylor, M.D.** Jefferson Medical College, Philadelphia, 1851, the oldest practitioner in Westmoreland County, Pa., died at his home in West Fairfield, April 30, aged 85.

**Leonard P. Holden, M.D.** Pennsylvania Medical College, Philadelphia, 1858, for nearly thirty years a practitioner of Boston, died at his home in that city, April 20, aged 78.

**Philip F. Fulmer, M.D.** University of Pennsylvania, 1853, of Dingman's Ferry, Pa., died suddenly from heart disease at Middletown, N. Y., April 29, aged 80.

**James P. Lytle, M.D.** Washington University, St. Louis, 1874, a former resident of Princeton, Ill., died at Anna, Ill., from cerebral hemorrhage, April 19.

**William L. Grim, M.D.** Western Reserve University, Cleveland, Ohio, 1875, died from pneumonia at his home in West Washington, Pa., April 24, aged 63.

**Henry Harrison Arnold, M.D.** University of Heidelberg, Germany, died at his home in Washington, D. C., April 20, after a long illness, aged 54.

**F. Antes Canfield, M.D.** Rush Medical College, 1872, the pioneer physician of Juneau County, Wis., died at his home in Necedah, April 22, aged 71.

**Fernando C. Gay, M.D.** St. Louis College of Physicians and Surgeons, 1888, of Alto Pass, Ill., died after a prolonged illness, April 26, aged 54.

**J. Walter Rowland, M.D.** Kansas City (Mo.) Medical College, 1895, of Herndon, Kan., was shot and killed by an unknown person, April 28.

**Edward T. Tinch, M.D.** Medical College of Ohio, Cincinnati, 1878, died at his residence in Freetown, Ind., April 20, after a long illness.

**James H. Crain, M.D.** College of Physicians and Surgeons, New York, 1850, died at his home in Beechwood, Ill., April 28, aged 74.

**Levi E. Pickett, M.D.** Rush Medical College, 1897, died at his home in Lineville, Iowa, April 22, after a short illness, aged 28.

**John W. Roe, M.D.** Omaha Medical College, 1884, died at the Presbyterian Hospital, Omaha, April 24, after a long illness, aged 74.

**William M. Wilson, M.D.** Southern Medical College, Atlanta, Ga., 1887, died at his home in Cleveland, Tenn., April 18.

**E. Fred Russell, M.D.** Rush Medical College, a physician of Poynette, Wis., died at Madison, Wis., April 29, aged 68.

**Joseph P. Turner, M.D.** Jefferson Medical College, 1878, died at his home in Trenton, N. J., April 27, aged 79.

## Societies.

### COMING MEETINGS.

**American Medical Association,** Saratoga Springs, N. Y., June 10 to 13.

**American Therapeutic Society,** New York City, May 13, 1902.

**Utah State Medical Society,** Salt Lake City, May 13-14, 1902.

**Oklahoma Territory Medical Association,** Oklahoma City, May 14, 1902.

**Arkansas Medical Society,** Little Rock, May 13-15, 1902.

**New Hampshire Medical Society,** Concord, May 15-16, 1902.

**Illinois State Medical Society,** Quincy, May 20-22, 1902.

**Medical Association of the State of Missouri,** St. Joseph, May 20-22, 1902.

**Arizona Medical Association,** Tucson, May 21-22, 1902.

**Medical Society of West Virginia,** Parkersburg, May 21-23, 1902.

**Medical Association of Montana,** Anaconda, May 21-22, 1902.

**Iowa State Medical Society,** Des Moines, May 21-23, 1902.

**Indiana State Medical Society,** Evansville, May 22-23, 1902.

**American Pediatric Society,** Boston, May 26-28, 1902.

**American Laryngological Association,** Boston, Mass., May 26-28, 1902.

**American Gynecological Society,** Atlantic City, May 27, 1902.

**Connecticut Medical Society,** New Haven, May 28-29, 1902.

**Ohio State Medical Society,** Toledo, May 28-30, 1902.

**American Laryngological, Rhinological and Otolological Society,** Washington, D. C., June 2-4, 1902.

**American Surgical Association,** Albany, N. Y., June 3-5, 1902.

**Louisiana State Medical Society,** Shreveport, June 3-5, 1902.

**Maine Medical Association,** Portland, June 4-6, 1902.

**Rhode Island Medical Society,** Providence, June 5, 1902.

**Wisconsin State Medical Society,** Milwaukee, June 4-6, 1902.

**South Dakota State Medical Society,** Scotland, June 4-5, 1902.

**Association of Military Surgeons of the United States,** Washington, D. C., June 5-7, 1902.

**American Orthopedic Association,** Philadelphia, Pa., June 5-7, 1902.

**American Academy of Medicine,** Saratoga Springs, N. Y., June 7, 1902.

**American Association of Life Insurance Examining Surgeons,** Saratoga Springs, June 9, 1902.

**National Confederation State Medical Examining and Licensing Boards,** Saratoga Springs, N. Y., June 9, 1902.

**Association of American Medical Colleges,** Saratoga Springs, N. Y., June 9, 1902.

**American Climatological Association,** Los Angeles, Cal., June 9-11, 1902.

**American Proctological Association,** Saratoga Springs, N. Y., June 10, 1902.

**Medical Society of Delaware,** Newark, June 10, 1902.

**Massachusetts Medical Society,** Boston, Mass., June 10-11, 1902.

**Medical Society of the State of North Carolina,** Wilmington, June 10-14, 1902.

**Colorado State Medical Society,** Pueblo, June 17, 1902.

**American Medico-Psychological Association,** Montreal, June 17-20, 1902.

**Minnesota State Medical Society,** Minneapolis, June 18, 1902.

**Medical Society of New Jersey,** Atlantic City, June 24-26, 1902.

**Washington State Medical Society,** Tacoma, June 24-26, 1902.

**Michigan State Medical Society,** Port Huron, June 26-27, 1902.

**Association of Central-Railway-of-Georgia Surgeons.**—At the annual meeting of this Association in Savannah, April 15, Dr. James B. Morgan, Augusta, was elected president.

**Delta County (Mich.) Medical Society.**—The annual meeting of this Society was held in Gladstone, April 23. Dr. David N. Kee, Gladstone, was elected president; Dr. H. W. Long, secretary, and Dr. Andrew Nelson, Escanaba, treasurer.

**New Haven County (Conn.) Medical Society.**—At the semi-annual meeting of this Society, held in Ansonia, April 17, Dr. P. Frederick Metz, formerly a practitioner of New Haven, was formally expelled from the Society on account of illegal practices.

**Mercer County (Ill.) Medical Society.**—At a meeting of physicians at Aledo, April 17, preliminary steps were taken to

form a county medical society. Dr. George Irwin, Aledo, was made temporary chairman and Dr. Albert N. Mackey, Aledo, temporary secretary.

**Bristol North District (Mass.) Medical Society.**—At the annual meeting of this Society, April 18, Dr. Charles S. Holden, Attleboro, was elected president; Dr. W. V. Fox, Bristol, vice-president and treasurer; Dr. Ralph D. Dean, secretary, and Dr. H. B. Baker, librarian.

**Rockland County (N. Y.) Medical Association.**—This Association held its annual meeting at Suffern, April 16. Dr. Gerrit F. Blauvelt, Nyack, was elected president; Dr. Daniel B. Van Wagenen, Suffern, vice-president, and Dr. Norman B. Bayley, Haverstraw, secretary.

**Austin Flint Medical Association.**—At the annual meeting of this body held at Osage, Iowa, April 15, Dr. J. Clinton Powers, Hampton, was elected president; Dr. John C. Wright, Clear Lake, Iowa, vice-president, and Dr. Lester C. Kern, Waverly, Iowa, re-elected secretary.

**Hill County (Texas) Medical and Surgical Association.**—This body met at Hillsboro, April 14, and elected Dr. James J. Robert, Hillsboro, president; Dr. James A. Adams, Hillsboro, vice-president; Dr. J. M. Martin, Massey, secretary, and Dr. Allen J. Gilbert, Hillsboro, treasurer.

**Fond du Lac County (Wis.) Medical Association.**—At a meeting of physicians held in Fond du Lac, April 23, it was decided to form a county medical organization. Dr. Stephen E. Gavin, Fond du Lac, was elected temporary president, and Dr. Guy T. Boyd, temporary secretary.

**Middlesex County (Conn.) Medical Society.**—This Society, at its one hundred and tenth annual meeting, held in Middletown, April 23, elected Dr. Frank E. Potter, Portland, president; Dr. Charles H. Hubbard, Essex, vice-president, and Dr. Frank K. Hallock, Cromwell, clerk.

**Windham County (Conn.) Medical Society.**—This Society convened for its one hundred and ninth annual session at Wilimantic, April 19. Dr. Frank H. Coops, Danielson, was elected president; Dr. Henry R. Lowe, Putnam, vice-president, and Dr. James L. Gardner, Cental Village, clerk.

**Detroit Medical Society.**—The annual meeting of this Society for election of officers was held, April 30, at which the following officers were elected: Dr. Frank B. Tibbals, president; Dr. Willis S. Anderson, vice-president; Dr. Louis J. Goux, secretary, and Dr. H. Wellington Yates, treasurer.

**Johnson County (Ill.) Medical Association.**—About twenty physicians of Johnson County met at Vienna, April 24, and organized a county association with the following officers: Dr. John McC. Damron, president; Dr. Newton J. Benson, vice-president, and Dr. Thomas E. McCall, secretary and treasurer.

**Blue Earth County (Minn.) Medical Society.**—This Society was reorganized at Mankato, April 21, along the lines suggested by Dr. Thomas McDavitt, secretary of the Minnesota State Medical Society. Officers were elected and Dr. J. Francis Shefeik, Mapleton, was elected a delegate to the State Society.

**Macon County (Mo.) Medical and Surgical Society.**—The annual election of this Society, held at Macon, April 22, resulted as follows. Dr. Charles W. Reagan, Macon, president; Dr. George F. Brewington, Bevier, vice-president; Dr. George B. Rush, Macon, secretary, and Dr. Benjamin J. Milam, Macon, treasurer.

**Tolland County (Conn.) Medical Society.**—The annual meeting of this Society was held at Rockville, April 15. Dr. Eli P. Flint, Rockville, was elected president; Dr. Alonzo L. Hurd, Somers, vice-president; Dr. Edwin T. Davis, Ellington, secretary and treasurer, and Dr. Cyrus B. Newton, Stafford Springs, county reporter.

**Macoupin County (Ill.) Medical Society.**—This Society convened in Carlinville for its semi-annual session, April 22. The following officers were elected: Dr. Harry W. Gobble, Carlinville, president; Dr. Noah A. Crouch, Chesterfield, vice-president, and Dr. J. Palmer Matthews, Carlinville, permanent secretary and treasurer.

**Plymouth District (Mass.) Medical Society.**—This Society held its annual meeting at Brockton, April 16, and elected the following officers: Dr. Jesse H. Averill, Campello, president; Dr. William P. Chisholm, Brockton, vice-president; Dr. Frank H. Burnett, Brockton, secretary, treasurer and reporter, and Dr. Charles E. Lovell, Whitman, librarian.

**Knox County (Ill.) Medical Society.**—At a meeting of Knox County physicians at Galesburg, April 22, a county society was organized with the following officers: Dr. Louis

Becker, Knoxville, president; Dr. Guy A. Longbrake, Galesburg, vice-president; Dr. George S. Bower, Galesburg, secretary, and Dr. Frederick G. Hall, Galesburg, treasurer.

**Eastern Ohio Medical Society.**—This Society, at its regular spring meeting, held in East Liverpool, April 24, took the initiatory step in a movement for the establishment of a state hospital for the treatment of tuberculosis and passed resolutions very strongly indorsing such an institution.

**American Academy of Medicine.**—The twenty-seventh annual meeting of the Academy will convene at the Kensington, Saratoga, June 7, and continue during Monday, June 9. A feature of the meeting will be an address by Edward T. Devine of the United Charities of New York, on "Co-operation of the Medical Profession in Charitable and Social Reform."

**Brainerd District (Ill.) Medical Society.**—The twenty-fifth annual and silver jubilee meeting of this society was held at Mason City, April 24. The following officers were elected: President, Dr. W. P. Walker, Mason City; vice-president, Dr. William V. Guttery, Middletown; secretary, Dr. James L. Lowrie, Lincoln, and treasurer, Dr. Charles C. Reed, Lincoln.

**Guilford County (N. C.) Medical Society.**—The organization of a county medical society was perfected at Greensboro, April 19. Dr. Millard F. Fox, Guilford College, was elected president; Dr. David A. Stanton, High Point, first vice-president; Dr. Albert R. Wilson, Greensboro, second vice-president; and Dr. Charles L. Scott, Greensboro, secretary and treasurer.

**Worcester North District (Mass.) Medical Society.**—The forty-fourth annual meeting of this Society was held at Fitchburg, April 22. Dr. Charles E. Bigelow, Leominster, was elected president; Dr. H. Porter Hall, Leominster, vice-president; Dr. Walter F. Sawyer, Fitchburg, secretary; Dr. Eustace L. Fiske, Fitchburg, treasurer, and Dr. Atherton P. Mason, Fitchburg, librarian.

**District Medical Society of Hunterdon County, N. J.**—This Society held its annual meeting in Flemington, April 22. The following officers were elected: Dr. Howard Servis, Junction, president; Drs. William H. Schenck, Flemington, and Leon T. Salmon, Lambertville, vice-presidents; Dr. I. S. Cramer, Flemington, secretary; Dr. Obadiah H. Sproul, Flemington, treasurer, and Dr. George N. Best, Rosemont, reporter.

**District Medical Society of the County of Middlesex, N. J.**—The annual meeting of this Society was held in New Brunswick, April 18. Dr. Edward E. Haines, South Amboy, was elected president; Dr. William E. Ramsay, Perth Amboy, vice-president; Dr. David Stephens, New Brunswick, secretary; Dr. David C. English, New Brunswick, treasurer, and Dr. Arthur L. Smith, New Brunswick, reporter.

**Windham County (Vt.) Medical Society.**—The physicians of Windham County met at Brattleboro and organized a county medical society, electing the following officers to serve until the annual meeting in September: Dr. Edward R. Campbell, Belkows Falls, president; Dr. Frederick L. Osgood, Townshend, vice-president; Dr. G. R. Anderson, Brattleboro, secretary, and Dr. Ansel I. Miller, Brattleboro, treasurer.

**Association of Medical Officers of the Army and Navy of the Confederacy.**—This Association held its annual meeting at Dallas, Texas, April 24. The following officers were elected: Dr. William J. W. Kerr, Corsicana, Texas, president; Drs. D. H. Key, Monroe, La., Jones C. Abernathy, Birmingham, Ala., Joseph S. Tipton, Roanoke, Va., and Joel C. Hall, Anguilla, Miss., vice-presidents, and Dr. Deering J. Roberts, Nashville, secretary and treasurer.

**Jo Daviess County (Ill.) Medical Society.**—This Society celebrated its second anniversary at Elizabeth, April 24. Dr. Henry T. Godfrey, Galena, was elected president; Dr. George E. Miller, Hanover, vice-president; Dr. Domer G. Smith, Elizabeth, secretary; Dr. Thomas J. Stafford, Stockton, treasurer; Dr. Alfonso C. Cibulka, Warren, delegate to State Medical Society, and Dr. James C. Egan, Hanover, alternate. The Society was tendered an elaborate banquet by Drs. William Hutton and Domer G. Smith, Elizabeth.

**Clark County (Ohio) Medical Society.**—A joint meeting of the Clark County Medical Society and the Springfield Academy of Medicine was held at Springfield, April 24, for the purpose of amalgamating into one society on the lines laid down by the American Medical Association. The meeting lasted until midnight, when the consolidation was effected as the Clark County Medical Society. The meeting was presided over by Dr. Read L. Bell, Springfield, and Dr. J. C. Easton, Springfield, acted as secretary.

**Litchfield County (Conn.) Medical Society.**—The one hundred and thirty-eighth annual meeting of this body was held at Winsted, April 23. Dr. Jerome S. Bissell, Torrington, was elected president; Dr. David R. Rodger, Woodbury, vice-president; Dr. Albert E. Cobb, Falls Village, clerk; Dr. William S. Richards, Winsted, county representative, and Drs. William L. Platt, Torrington, George H. Knight, Lakeville, Jerome S. Bissell, Torrington, and Albert E. Cobb, Falls Village, members of the consulting staff of Litchfield County Hospital, Winchester.

**New York County Medical Association.**—At the annual meeting of this Society, held April 21, Dr. Charles Warren Allen presented a paper on "Treatment of Cancer by the X-Ray," illustrated by lantern slides and also by a number of patients. The election of officers resulted as follows: Dr. Alexander Lambert, president; Drs. Wilbur B. Marple and Frederick P. Hammond, vice-presidents; Dr. Ogden C. Ludlow, secretary; Dr. Frederic W. Loughran, corresponding secretary; Dr. Charles E. Denison, treasurer; Dr. Parker Syms, member of executive committee, and Dr. E. Eliot Harris, member of nominating committee, Fifth District Branch.

**Public Health Association of California.**—Health officials, sanitarians and inspectors from various cities in California met, April 14, at San Francisco, with local officers to organize a state association and arrange for a regular annual convention. About thirty were present. The plan of organization was placed in the hands of a committee, who reported in favor of a permanent association and recommended plans, which were adopted. The election of officers resulted as follows: President, Dr. Edward Van Adelung, Oakland; vice-presidents, Drs. Sylvester B. Davis, Stockton, and William Simpson, San Jose; secretary and treasurer, James A. Emery, San Francisco.

**South Carolina Medical Association.**—This Association held its fifty-second annual meeting at Spartanburg, April 16 and 17, about 100 physicians being in attendance. The annual address was delivered by Dr. William T. English, Pittsburg, Pa., on "The Negro Problem from the Physician's Standpoint." The annual election of officers resulted as follows: President, Dr. Manning Simons, Charleston; vice-presidents, Drs. A. Frank Darby, Columbia, Peter L. Horn of St. Georges, and Peter G. Ellison, Newberry; recording secretary, Dr. T. Prioleau Whaley, Charleston; corresponding secretary, Dr. Augustus B. Knowlton, Columbia, and treasurer, Dr. Barnard E. Baker, Charleston. The Association will meet in 1903 at Sumter, April 15 and 16.

#### AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

*Sixteenth Annual Meeting, held at Atlantic City, April 29-30, 1902.*

President, William T. Belfield, M.D., Chicago, in the Chair.

#### Prostatectomy.

The first day was almost entirely devoted to the prostate gland and its removal. Dr. John P. Bryson, St. Louis, described the technic of prostatectomy and illustrated by cases and specimens. Dr. Charles H. Chetwood, New York City, spoke on the indications for operation.

#### Choice of Operation.

Dr. HENRY H. MORTON of Brooklyn reported a case in which Bottini's operation had been performed.

Dr. Charles L. Gibson, New York, presented a specimen of a "Removal in Toto of All Three Lobes of the Prostate by Suprapubic Cystotomy," for the purpose of emphasizing how easily the prostate, or portions of it, can be removed, without destruction of tissue or hemorrhage provided one only enters the essential line of cleavage.

After discussion by Drs. Eugene Fuller, New York; Francis S. Watson, Boston, and George Chismore, San Francisco, Dr. Bransford Lewis of St. Louis discussed "Operative Treatment." The conditions favorable for the several operations in vogue were summed up as follows:

**FAVORABLE FOR THE SUPRAPUBIC ROUTE:** 1. General enlargement of the prostate, with extreme intravesical projection of the median or lateral lobes, diminishing their accessibility from the perineum. 2. Marked pedunculation of the intravesical tumors, with absence of obstruction from other sources.

**FAVORABLE FOR THE PERINEAL ROUTE:** 1. General hypertrophy, involving the lateral lobes, without extreme intravesical projection. 2. Large or very thick bar formation. 3. Severe compression of the urethra between massive lateral lobes. 4. Excessive development of the prostate in the direction of the rectum. 5. In most cases where the patient is in good general condition, is not too aged, and there is not a special indication favoring one of the other procedures.

**FAVORABLE FOR THE BOTTINI:** 1. Cases of extreme debility, or of extreme age, unable to stand one of the severer operations. 2. Cases of bar or median sessile obstruction, of not too great dimensions. 3. In complete collar formations. 4. Horwitz says it should be employed as a prophylactic against further obstructive tendency, at the beginning of catheter life.

DR. FRANCIS S. WATSON, Boston, read a paper on "The Phloridzin Test in Determining the Functioning Capacity of the Kidneys."

DR. F. L. STURGIS, New York, said that the removal of the prostate and ejaculatory ducts prevented the flow of the prostatic secretion, which was so essential to the vitality of the spermatozoa, and therefore tended to render the male sterile. On this account he believed that some partial operation, like the Bottini, was preferable.

Drs. Eugene Fuller and F. Tilden Brown of New York, and H. H. Young, Baltimore, and William T. Belfield, Chicago, continued the discussion.

The first day's session closed with a paper on "The Detection of Stone in the Kidney by Skiagraph, with Specimen," by Dr. James Bell, Montreal.

The second day was largely devoted to Genito-Urinary Tuberculosis.

#### Renal Tuberculosis.

DR. F. TILDEN BROWN, New York City, said that at the Presbyterian Hospital, during the past ten years, out of the 1427 necropsies, 258 (18 per cent.) showed tuberculous lesions somewhere in the body; 48 (18.5 per cent.) showed renal tuberculosis. Of these 48, 32 were males and 16 females; 39 had lesions in both kidneys, 9 in one kidney, 5 being in the right and 4 in the left kidney. In the 258 tuberculous bodies the kidneys were more commonly involved than the spleen, liver or adrenals. During the same time, there were in the hospital 78 cases diagnosed as renal tuberculosis; 13 (16 per cent.) had nephrectomy performed, with but one death occurring two months after the operation; at the autopsy the other kidney was found to be involved. The vast majority of autopsies showing tuberculous lesions in the kidney are of the disseminated military type. With such a class of patients, of course, surgeons have not to deal. At necropsies as high as 3 or 4 per cent. of healed pulmonary tuberculosis have been found; whereas it was of the rarest occurrence to find any evidence of Nature's efforts to cure renal tuberculosis. From a surgical standpoint he did not believe any surgeon would hesitate to perform an immediate nephrectomy if he were sure that one kidney contained the only appreciable focus of the tuberculosis.

#### Tuberculosis of the Seminal Tract.

DR. HUGH H. YOUNG, Baltimore, presented an exhaustive résumé of the literature, and his conclusions were as follows:

**PATHOLOGY.**—The disease may begin primarily anywhere in the tract, but it usually starts in the epididymis. The bacilli which are being constantly carried up with the testicular secretion along the vas deferens very soon localize in the ampulla of the vas, the ejaculatory duct, the seminal vesicle and the adjacent portion of the prostate. The testicle is very seldom the point of primary origin and it becomes involved secondarily generally much later than the seminal vesicles, though it seemed not to be so immune as formerly supposed. Tuberculosis frequently travels from the kidney to the prostate and from there involves the testicle, but it is almost never primary in the bladder.

**TREATMENT.**—There are to be found in literature 35 cases in which the seminal vesicles have been removed for tuberculosis; of these 14 will not be considered because the operator failed

to state ultimate results. Of the 21 which were followed, 6 died, 5 had recurrences and 10 were classed as well. Only 8 cases were followed over one year and, of these, 2 died, 2 had perineal fistulas and 4 were classed as cured. In only one of the six fatal cases was pulmonary involvement present before operation. Considering, then, that both seminal vesicles were involved in but 12 cases, the infrequency of lung and bladder tuberculosis, these 35 cases were not the most intensive, and with cures claimed in less than 50 per cent. and with only eight followed more than one year, the results obtained by operative removal of the tuberculous seminal vesicles were indeed unsatisfactory, and apparently not nearly so good as where a partial operation upon the external disease in the testicle alone is attempted.

DR. PAUL THORNDIKE, Boston, discussed Tuberculosis of the Testicle.

#### An Analysis of Ninety-Six Operations for the Relief of Tuberculosis of the Testicle.

DR. ORVILLE HORWITZ of Philadelphia presented the following conclusions to his paper: 1. A primary tubercular infection of either the epididymis or testicle may occur, the former being by far the more common. 2. A primary infection of the epididymis, secondarily that of the testicle, is more common than the descending one. 3. Primary involvement of either the epididymis or testicle usually takes place through the circulation; the soil being predisposed to the location of the tubercle bacillus either by a slight traumatism or by some infecting condition which has given rise to inflammation of the organ; most commonly an attack of gonorrhea. 4. Secondary tubercular involvement of the epididymis or testicle sometimes follows a primary focus of the disease in other portions of the body, more commonly in those organs that are in a direct anatomic connection with the sexual glands, such as the seminal vesicles, the prostate, urethra, bladder, ureter or kidney. 5. The invasion of the testicle may be rapid, associated with acute inflammatory symptoms, an abscess soon developing; or the onset may be slow, the symptoms simulating those of either chronic syphilitic orchitis or malignant disease of the organ. 6. The tuberculin test should always be employed in doubtful cases where only one focus of the disease is known to exist. 7. In doubtful cases associated with hydrocele, the fluid should be examined for the tubercle bacilli and inoculating experiments made. 8. The injections of either emulsions of iodoform or of sulphate of zinc into the diseased part are not to be recommended. 9. In all cases of encapsulated caseous nodules quiescent in the epididymis, epididymectomy should be performed. 10. Epididymectomy, together with resection of the vas deferens, is not attended by either atrophy of the testicle or sexual weakness. 11. The drainage of tubercular abscesses followed by the use of the curette is only to be employed where radical treatment is not permissible as it is attended with more or less danger and is generally unsatisfactory in its results. 12. In instances where the epididymis alone is involved, a resection of the diseased structure is all that is required; whether a partial or complete resection of the vas deferens is to be undertaken is still undecided. 13. Double orchectomy should be performed when both glands are diseased, provided there is not extensive co-existing tubercular infection of other organs. 14. Whether infected seminal vesicles should always be removed at the time that the epididymis or testicle is resected is a question open for discussion. From the fact that in a large majority of cases the removal of the primary seat of the disease is followed by a subsidence of the tubercular involvement of the vesicles, it is deemed wiser, as a rule, to wait and remove the vesicles later if necessary. 15. Hygienic and climatic influence play as important parts after operation in fortifying the constitution against further invasion as they do in other tubercular conditions. 16. The anti-tubercular remedies are of great value in controlling the disease and should be employed in conjunction with whatever surgical procedure may be deemed necessary.

#### Gangrene of Penis. Teratoma of Testicle.

DR. JAMES B. HAYDEN of New York reported one case of each of these unusual conditions with photographs.

DR. RAMON GUIERAS, New York City, read a paper on "The Surgical Treatment of Chronic Nephritis."

#### Officers for the Ensuing Year.

The election of officers resulted as follows: President, Dr. Paul Thorndike, Boston; vice-president, Dr. Edwin C. Burnett, St. Louis; secretary and treasurer, Dr. John Vanderpoel, New York City; council, Drs. William T. Belfield, Chicago, and James R. Hayden, New York City. The next place of meeting will be Washington, D. C.

#### WESTERN OPHTHALMOLOGIC AND OTO-LARYNGOLOGIC ASSOCIATION.

*Proceedings of the Seventh Annual Meeting, held at the Auditorium Hotel, Chicago, April 10-12, 1902, under the Presidency of Dr. Christian R. Holmes, of Cincinnati, Ohio.*

#### Thiosinamin and Electrolysis in the Treatment of Tubal Obstruction.

DR. J. C. BECK, Chicago, read this, the first paper. His observations in treating fourteen cases led him to conclude that without mechanical treatment the injections of thiosinamin did not materially improve the condition; but, after use in conjunction with electrolysis, a simple bougie could be passed with greater ease and inflation was more free and all the cases treated improved in all respects, as regards hearing, tinnitus aurium, general condition, etc. He also says that before using thiosinamin careful inquiry should be made for possible contra-indications to its use, such as existing chronic tuberculosis, malignant tumors and scars which support the abdominal organs in the abdominal wall, such as are found after laparotomy. The drug may be used with just as good results—though it is not as rapid in its action—by mouth administration as hypodermically.

#### Value of Electrolysis in the Eustachian Tube.

DR. NORVAL H. PIERCE, Chicago, epitomized the history of electrolysis and presented a brief review of the anatomy of the Eustachian tube, explaining certain points noted in the use of the electrical bougie in the tube which have been otherwise interpreted or understood. He reported 20 cases, in only two of which could any results be ascribed to the electric bougie. These were both cases of subacute disease, with recurrent attacks of defective audition and tinnitus, with diminishing intervals, with soft infiltrated membrano-cartilaginous tube near the isthmus. In both of these the benefit to audition and the subjective symptoms were marked, immediate and lasting, and these results were obtained after the usual method of injection, massage, etc.

He concludes: 1. In sclerotic disease electrolysis is useless. 2. In the great majority of cases of catarrhal disease it has no advantage over other methods of treatment. 3. In a few cases, where there is probably a soft exudate near the isthmus, it may be regarded of value.

#### President's Address.

DR. CHRISTAIN R. HOLMES, Cincinnati, Ohio, in lieu of the customary stereotyped presidential address, gave an illustrated lecture on the development of the ear from the lowest animal up to man.

#### Neighboring Parts of the Middle Ear and Their Infection.

DR. OTTO J. STEIN, Chicago, read this paper, the object of the contribution being simply to renew acquaintance with the anatomic surroundings of the middle ear. He reviewed the manner and avenues through which infection reaches the neighboring parts of the middle ear, and the manner in which involvement of such parts takes place. He mentioned two ways: first, by continuity of tissue, and, second, by way of the blood and lymph channels, independent of or associated with but not dependent upon any previous ear trouble, as in cases of syphilis and tuberculosis. Involvement by direct continuity of tissue might take place through carious destruction. This was probably the most frequent means of implication, especially in the adult, and almost always in chronic cases. In the acute forms and in children, this was probably less so. Other means of involvement were numerous. It might take place by way

of numerous emissary and communicating blood channels, or by way of the lymph or nerve channels, etc. In the case of the antrum and mastoid cells, the auitus furnishes the avenue through which infection travels. Finally, the parotid gland on the lateral wall of the pharynx may become implicated in an infective process from the middle ear, owing to its anatomic relationship to the fissure of Glasseri.

DR. B. ALEXANDER RANDALL, Philadelphia, delivered a lantern lecture, by invitation, in which he pointed out the relation of the facial nerve to the tympanum, especially in tympanic exenteration.

#### Principles of the Treatment of Otorrhea.

DR. WILLIAM L. BALLENGER, Chicago, read a paper on this subject. The treatment of suppurative processes of the middle ear and mastoid spaces should be based upon three principles: first, the establishment and maintenance of free drainage of pus and secretions; second, the removal of all morbid material, whether it be pus, debris, or sequestra of bone; third, the maintenance of asepsis of all parts. He discussed the treatment of suppuration limited to the middle ear proper, saying that it might be successfully accomplished by simple local treatment through the external meatus. But as to the middle ear attic, and antrum, the narrowness of the aditus materially interferes with the free drainage of the antrum, hence treatment through the external auditory meatus is usually inadequate. In a certain number of cases the removal of the malleus and incus, with the drum-head, affords ample drainage and enables the principles of treatment to be carried out. In cases of suppuration involving the middle ear, attic, antrum and mastoid cells, he said it was often necessary, in addition to other treatment, to resort to the radical mastoid operation in order to eradicate the disease.

DR. M. A. GOLDSTEIN, St. Louis, Mo., discussed the post-operative management of cases of intra-nasal surgery.

#### The Best Means of Removing Nasal Obstructions.

DR. J. W. MURPHY, of Cincinnati, Ohio, followed with this paper. He finds himself resorting to the cautery less and less each year, since his experience has been that more damage results from repeated cauterizing than follows a clean surgical operation along the under-surface of the bone, where the glands are few and the hypertrophied tissue is most marked. The operation which he has practiced for several years consists in removing the redundant tissue by means of saw and scissors. He always aims to remove a very small portion of the under-edge of the bone. Often this sliver of bone is so small that it is scarcely perceptible, but the success of the operation consists in getting a linear scar along the entire under edge of the turbinate body, since it is by means of this scar that the permanency of the opening is to be maintained, and the blood supply cut off from the underlying connective tissue. During the past ten years he has had occasion to do this operation 263 times on 155 patients, and in about 2 per cent. of his cases there has been a regeneration of tissue at the site of operation. In the removal of the middle turbinate, he finds the scissors devised by Dr. C. R. Holmes admirably adapted for this purpose.

The advantages of operating with the saw and scissors are that the technique is simple, the instruments required are few and inexpensive and no cauterizing outfit is necessary. The parts operated upon are constantly under the eye and direct control of the surgeon and as much or as little tissue as is necessary can be removed. The operation requires but a few moments, is painless, bloodless and, as a rule, the results are permanent. He has operated upon a number of medical men and they have all experienced permanent relief. Indeed, the operation has been so satisfactory, both to himself and patients, that he seldom resorts to any other method.

DR. G. V. I. BROWN, Milwaukee, Wis., discussed "The Dynamics of Nasal Disease in Relation to the Maxilla."

#### The Fauical Tonsil and Submerged Tonsil.

DR. E. O. Sisson, Keokuk, Iowa, contributed a paper on "The Hypertrophied Fauical Tonsil; with a Report of the Morbid Histology of the So-called Submerged Tonsil." He discussed the various forms of hypertrophy of the fauical ton-

sil and the treatment of the same. The paper included a report on the morbid histology of the so-called "submerged tonsil," first described by Pyncheon, where the originally hypertrophied tonsil has become partially atrophied and largely submerged, the submersion being as much due to pillar hypertrophy as to tonsil atrophy.

A microscopic examination of a large number of specimens of such tonsils furnished the author by Dr. Pyncheon showed a great increase of connective tissue. It formed broad bands throughout the gland, leaving little islands of lymphoid cells scattered through it, and in some cases formed large numbers of well-defined alveoli containing lymphoid cells, causing the specimens to assume the appearance of a scirrhus carcinoma, the lymphoid cells taking the place of the epithelial cells. The blood vessels in the connective tissue were much larger than those seen in the normal condition. The laminated epithelial covering was a good deal thickened. Beneath the epithelium the mucosa was seen to be increased by the extra development of lymphatic cells, some of which in places insinuated themselves between the epithelial cells. The acinous mucus glands naturally present in the tonsil had disappeared in the majority of specimens examined.

In treatment, the following conclusions were given: 1. Only the surgical treatment yields satisfactory results. 2. No one method is applicable to all cases. 3. The danger from hemorrhage is slight and should not deter one from taking operative steps in all cases where they are indicated.

#### The Misuse of Glasses.

DR. F. C. HOTZ, Chicago, delivered an address on this subject. The careful adjustment of glasses for the accurate correction of errors of refraction has achieved so many brilliant results that refraction work is now a very prominent, if not the most prominent, part of ophthalmic practice. But neither science nor common sense can approve the prescribing of glasses for slight refraction errors in cases where the apparent asthenopia is plainly due to conjunctivitis, blepharitis or other local or general disorders.

#### Section and Exsection of the Rectus Muscle in Case of Paralysis, for Cosmetic Purposes.

DR. A. E. PRINCE, Springfield, Ill., advocated the division of the muscle or exsection of a greater or less portion of the muscle in cases of paralysis in which an advancement was not indicated. His experience is that all attempts at correcting the deformity of confirmed paralysis of the rectus will be failures unless the muscle is weakened to correspond with the paralyzed muscle.

DR. J. ELLIOT COLBURN, Chicago, read a paper in which he discussed the present state of our knowledge concerning so-called partial or graduated tenotomies and the heterophorias.

DR. DERRICK T. VAIL, Cincinnati, Ohio, reported a case of sympathetic ophthalmia, with complete recovery of both eyes. His principal object was to lay especial stress upon the value of the one great therapeutic agent—total darkness—complete rest for the retina and accommodation, in the treatment of sympathetic ophthalmia and allied affections of the eye.

DR. A. ALT, St. Louis, Mo., followed with a lantern lecture on epithelial intra-ocular tumors.

DR. C. L. MINOR, Springfield, Ohio, discussed "Refraction; Its Difficulties, and How to Overcome Them."

DR. J. O. STILLSON, Indianapolis, Ind., reported cases of bleaching or distinct pallor of the temporal segment of papulo-macular bundle of optic nerve fibers, due to other causes than tobacco and alcohol.

DR. DUDLEY S. REYNOLDS, Louisville, Ky., followed with a paper on "Toxic Amblyopia," selecting for purposes of illustration a case of nearly total blindness, the result of drinking essence of cinnamon; a typical case of autotoxemia, and four cases of tobacco amblyopia in persons who had never taken alcohol.

#### Is the Dislocation of the Lens into the Vitreous Ever Justifiable?

DR. GEORGE F. SUKER, Chicago, summed up the most salient points of his paper as follows:

1. The percentage of failures in the class of cases in which

depression can be performed is no larger, on the contrary less, than in the same cases operated upon by extraction.

2. Do not depress a lens in cases with choroiditis or retinitis.

3. Consider depression in all cases where one eye has been lost by extraction, and its fellow must be operated upon.

4. Depression of the lens must not be indiscriminately performed, but only in such cases where the contra-indications of extraction outweigh its own objections.

Finally, the writer considers reclinacion of the lens as an exceptional procedure, and can only regard it as unquestionably indicated in such a class of cases as he had alluded to, when the general constitution of the patient, or the previous experience with the fellow eye, unhesitatingly points to a failure if the extraction method were resorted to.

DR. O. A. GRIFFIN, Ann Arbor, Mich., read a paper on "Transient Astigmatism."

#### Ocular Affections Secondary to Syphilis.

DR. RANDOLPH BRUNSON, Hot Springs, Ark., read a paper on this subject, in which he said that syphilis is probably responsible for a greater number of ocular affections than any one disease known. Secondary syphilitic ulcers may occur on the eyelids from the breaking down of a gumma originating in the skin or in the subcutaneous tissue and cartilage. The most frequent location of the lesion is in the skin near the lid margin or below the inner canthus, although it may occur on the conjunctival surface of the lid. The conjunctiva is very rarely affected primarily, but inflammation usually occurs when the iris and ciliary body are involved the edema observed in these cases being caused by an obstruction of the return-flow of circulation.

The lachrymal sac and duct are frequently invaded by syphilis through the nose. In all the cases of stricture of the lachrymal canal, due to syphilis, which had come under his notice, he had always been able to find the cause in the nose. Syphilitic rhinitis, both acute and chronic, is very common, and when there was great destruction of the nasal bones and membranes, dacryo-cystitis usually occurs, with varying severity. The iris and ciliary body are perhaps more often invaded by syphilis than any one part of the globe, and syphilis is frequently the common predisposing cause of iritis. About 70 per cent. of all cases of iritis are caused by this disease. The author has found in examining the histories of 1500 cases of syphilis, that iritis occurred in over 3 per cent. of all cases.

He mentioned a number of characteristic signs which enable one to recognize the etiology of the disease, the most conspicuous of which are the papules, small raised masses in the iris, usually not exceeding three in number, and generally located in the pupillary zone, but may be seen at the periphery of the anterior chamber, or elsewhere.

Interstitial keratitis had its origin in syphilis, and in perhaps 60 per cent. or more of all cases of this variety of disease of the cornea it is hereditary. He had never seen a case caused by acquired syphilis, and believes the cases reported as such have simply been produced by iridochoroiditis, which has involved the deeper layer of the cornea. Disseminated choroiditis is caused by syphilis in perhaps 80 per cent. of all cases.

#### Enucleation of Blind Eyes Caused by Traumatism.

DR. C. D. WESCOTT, Chicago, urged this measure.

Ever since his pupillage in ophthalmology he has had a prejudice against hopelessly blind eyes, made so by traumatism, or inflammation of the anterior segment of the globe. The fact that there is a well-known difference of opinion as to what ophthalmologists should do or recommend in such cases is his excuse for speaking on the subject. As an illustration of what may happen in consequence of leaving a blind eye from traumatism, in spite of the fact that the eye is quiet, not shrunken, not painful, not tender, he recounted two or three cases in which sympathetic ophthalmitis destroyed the well eye.

Dr. Wescott's treatment in this and other cases was endorsed, in the discussion, by Drs. Eugene Smith, A. Alt and George F. Suker.

### Estimation of Damages in Eye Injuries.

DR. H. V. WUERDEMANN, Milwaukee, Wis., read a paper entitled "Epieritic Remarks upon Methods for Estimating the Economic Damage from Accidental Injuries to the Eyes." Earning ability is economically synonymous with visual earning ability for the majority of trades and professions. Injury to vision generally necessitates loss of earning powers. The economic value of vision is equivalent to the wages of the individual. After injuries involving loss of earning ability, the loss of wages may be reckoned from experience in examining large numbers of individuals, or the probable loss in any given case may be found by reckoning the percentage of damage to the normal function and applying this to the calculation of the probable pecuniary loss. A mathematical formula may be made for this purpose in which the several factors comprising vision should be properly related, and this formula for working vision should be modified by the ability to use the eyes for gainful purposes, the whole forming a formula for the earning ability. By this means a percentage of the loss to the earning ability may be figured and this percentage applied to the probable wages and duration of working life in the individual who has received the accident. Damages to ambition, to hopes and plans can not be considered. We must deal with the station in life, and expectation of wages and life which belongs to the individual at the time of the accident. Compensation for injuries from accidents to the eyes should be based upon the economic damage modified by the present rulings of American courts in allowing an empiric amount for pain, suffering and mental anguish and for philanthropic or punitive purposes, or for contributory negligence; the latter amounts being only of forensic importance. By the rules of Magnus and Wurdemann, the economic damage may be calculated in a manner fair and just to all interested parties.

DR. HANAU W. LOEB, St. Louis, Mo., reported a case of rapidly fatal carcinoma of the epipharynx. He went extensively into the literature of carcinoma of the epipharynx, epitomized the histories of 27 cases which he had found and gave the symptomatology.

### Pneumatic Massage in Aural Practice.

DR. EDWIN PYNCHON, Chicago, read this paper. Through its favorable effect upon the cause—middle-ear adhesions, etc.—pneumatic massage is often beneficial. It assists greatly in the correction of itching of the external auditory canal and is generally instrumental in increasing the secretion of wax when the canal has become too dry, both conditions being concomitant with chronic catarrhal otitis media. Additionally, in hypertrophic cases, inflation by the Politzer method soon becomes more easy of execution.

With reference to the value of pneumatic massage in acute inflammatory troubles of the middle-ear, authorities differ. Pneumatic massage has proved of value in suppurative conditions of the middle-ear, particularly in cases of long-standing, and when employed in addition to the usual line of treatment will often greatly expedite a cure, owing to its mechanical effect in jarring or drawing down discharges from the attic.

### The Significance of Aphonia in Aneurysm of the Arch.

DR. WILLIAM PORTER, St. Louis, Mo., believes that early diagnosis and proper care will increase the life expectancy and comfort of the patient. Pressure on the recurrent nerve does not always produce aphonia. Sometimes there is arytenoid compensation and the crossing of the median line by the one cord, while the other is in the cadaveric position. Unilateral congestion, or loss of symmetry of movement, is always suggestive. The laryngeal evidences of pressure may also be sequences of interference with nerve function by tumors or enlarged glands.

### Officers for the Ensuing Year.

These officers were elected: President, Dr. Wm. L. Ballenger, Chicago; first vice-president, Dr. J. O. Stillson, Indianapolis, Ind.; second vice-president, Dr. J. Morrison Ray, Louisville, Ky.; third vice-president, Dr. Edwin Pynchon, Chicago; secretary, Dr. Derrick T. Vail, Cincinnati, Ohio; treasurer, Dr. O. J. Stein, Chicago. Indianapolis, Ind., was selected as the place for holding the next annual meeting.

### CHICAGO NEUROLOGICAL SOCIETY AND CHICAGO MEDICAL SOCIETY.

*Joint Meeting, held April 2, 1902.*

President, Dr. Daniel R. Brower, In the Chair.

### Definition and Pathology of Multiple Neuritis.

DR. ARCHIBALD CHURCH spoke on the definition of neuritis, reviewed the etiology and described at some length the pathology.

DR. SYDNEY KUH discussed the "Symptomatology, Diagnosis and Differential Diagnosis of Neuritis."

### Treatment of Neuritis, Other Than Surgical.

DR. ELBERT WING read this paper. The objects of treatment are removal of the cause and restoration to normal conditions. Relief of pain is imperative in all acute cases of severity. For this purpose hot cloths properly applied along the course of the nerve often are of great effectiveness. Counter-irritation may answer, but should never be applied in the area of distribution of the affected nerve. In chronic cases the actual cautery is the best counter-irritant. In acute simple cases, sand bags, slings and splints have a useful function. They may promote relief of pain through limitation of motion and prevent and correct deformities. In most severe primary cases morphin is needed for the relief of pain. The coal-tar preparations rarely suffice. If used, the doses must be large, frequently repeated, and acetanilid should never be used for this purpose. Morphin, cocain and other analgesics are most effective when placed, by means of a hypodermic syringe, in the immediate proximity of the affected nerve. Stretching of the nerve, in simple sciatic cases, by forcible flexion of the trunk upon the extended lower extremities, or of the extended extremity upon the trunk, the body supine, is at times remarkably successful, both in relieving pain and promoting recovery. The same is true of efficient massage. The use of the electrostatic currents and the Roentgen ray have a useful future in the relief of pain in probably all cases of neuritis.

In the list of general tonics, the salts of strychnia rank first. As in any other chronic condition, the form of tonic used must be occasionally varied. In the chronic forms of simple neuritis the use of one grain of blue pill, two or three times daily, and for long periods, produces favorable results, not simply chronologic. In polyneuritic cases, massage, skillfully used, the proper use of splints and electricity, together with voluntary exercise of muscles, bring about cures even in the worst cases. As a rule, in alcoholic neuritis, alcohol may be withdrawn at once.

The causes of death in the fatal cases indicate clearly the special care which is needed, cardiac and pulmonary weakness being induced both directly by the special cause in each case and by the auto-intoxication which may arise in any case.

### Surgical Treatment.

DR. WELLER VAN HOOK discussed this phase of the subject, saying that surgery is in a position to be of service in the treatment of the consequences of neuritis rather than in the management of the actual disease itself, whether acute or chronic. Surgical means are indicated where pressure upon a nerve is inducing neuritis, especially where fractures primarily or secondarily involve large nerve trunks, or plexuses. Other conditions are compression by periostitis, or tumors of a non-malignant character.

When paralysis is a consequence of neuritis, surgery offers relief in many cases by transplantation of nerves or of tendons. Results obtained by this modern method of treatment are very gratifying. French surgeons, at the head of whom is Chipault, have of late shown much enthusiasm in the management of many cases of peripheral nerve disease, particularly of the trophic varieties, by stretching. It is claimed by Chipault that *mal perforant* of the foot can be favorably influenced in many instances by the stretching of the nerves of the leg. It is particularly in cases where the sciatic has been injured, or where it has been involved in inflammations of the thigh, that nerve stretching has seemed to be of service in *mal perforant*.

### Sciatica.

DR. L. HARRISON METTLER referred to sciatica being in some recent text-books still classified under several heads, as, for

instance, primary\* and secondary. The primary are divided into the idiopathic and the special forms of neuritis. He thought this was a mistake. He could not conceive of a secondary sciatica in the sense of a mere pain of the nerve caused by some extraneural pressure. If there is disease of the bone, tumor or other condition causing secondary disease, either of an inflammatory or degenerative type, in the sciatic nerve, it might seem to be a secondary sciatica, but it is only secondary etiologically. It is really a sciatic neuritis; hence he thought so-called secondary neuralgia, or sciatica as a special class, should be dropped from the books. Almost all the cases he had seen of sciatica exhibited more or less the symptoms of sciatic neuritis. The symptoms which usually accompany so-called ordinary idiopathic neuralgia of the sciatic nerve were those that are characteristic of sciatic neuritis.

As to the treatment in cases of sciatic neuritis, where there was a rheumatic diathesis, he obtained the most favorable results from the use of the salicylates, pushing them until he got a decided physiologic effect. He had not seen such favorable results from the use of mercury or antisyphilitic treatment. Sciatica was not usually caused by syphilis.

DR. DANIEL R. BROWER had had within three months two cases of neuritis of the fifth nerve, both syphilitic. It was rare in his experience for this nerve to be attacked by the syphilitic poison, but these cases, coming so close together, were interesting as well as instructive.

DR. C. P. PRYX said that dentists had a good deal to do with neuralgia of the fifth nerve. He was a little surprised on being told by a prominent neurologist that neuralgia of the fifth nerve was seldom caused by tooth irritation. Frequently the patients consult dentists for relief after they have gone through the gamut of the general treatment by physicians, and tooth irritation is found to be the cause. Often there is calcification of the tooth pulp, sometimes complete, at other times simply a calcified nodule, which caused the whole disturbance. The removal of this nodule effects a cure.

DR. O. B. WILL, Peoria, believes that in the acute or primary form of neuritis, where the patient was suffering much from neuralgia, the best treatment was the administration of chloroform or ether. He used this altogether in his own case, and his professional friends had adopted it, with good results.

DR. A. W. BAER had used the salicylates in the rheumatic form of neuritis, with beneficial results, especially if not pushed to the point of interfering with the functions of the stomach. He had never obtained much benefit or relief in these cases from external application, outside of heat and cold, except from the effects of rubbing oil on the parts affected. If the neuritis was of traumatic origin, the interrupted galvanic current was by all odds the best, and he had obtained some excellent results from it. Sparks from the static current in cases of toxic neuritis had given excellent results.

DR. JULIUS GRINKER said diphtheritic paralysis was nothing but a neuritis following diphtheria infection manifesting itself by motor disturbances principally, the sensory disturbances taking a back ground or perhaps not being noticed. He thought possibly many cases of sudden death after diphtheria were due to vagus involvement, the neuritis having developed and progressed rapidly and involved the vagus, killing the child, the nature of the trouble being unnoticed by the physician. Symptoms should be looked for in every case of diphtheria that has apparently recovered. He urged that the reflexes be tested, as the first symptom noted after diphtheria of oncoming neuritis was absence of reflexes. When the reflexes are diminished or absent, one should look out for neuritis. He narrated a case of paralysis of almost all the ocular muscles occurring after diphtheria in a child whom he cured by giving 1-30 gr. of strychnia, t. i. d.

DR. G. W. HALL said it was important to remember, in making a diagnosis, that sensory disturbances do not necessarily have to be present. He emphasized the great difference as to the presence and absence of sensory disturbances in the different forms of neuritis, saying that in neuritis following lead poisoning the sensory disturbances were very slight as compared with the motor. In neuritis following alcoholism it was very rare that we did not have sensory disturbances present to a greater or less extent. He believes in many cases

paralysis comes on almost simultaneously with sensory disturbances.

DR. LISTON H. MONTGOMERY would not care to use such large doses of strychnia as mentioned by Dr. Grinker. Diet was a very important feature in the treatment of many cases of neuritis.

DR. GRINKER did not consider the thirtieth of a grain of strychnia, administered to a child of eight or twelve years of age, a large dose. He had used it in such doses in several cases, with excellent results.

DR. I. A. AER believed that strychnia is frequently given to children in too large doses, and related a case. During the infantile period he believes great caution should be exercised in the administration of this drug.

DR. JAMES W. WALKER mentioned the use of the Paquelin cautery, saying that he had obtained excellent results in the relief of pain, but he could say nothing regarding its effect upon the inflammatory process in acute neuritis. It seemed formidable to the average practitioner to see it used. The lightest possible touch was all that was necessary. It could be used once daily, or once every other day, two or three strokes being made in the vicinity of the painful joint or nerve.

DR. THOMAS L. GILMER said he had been a sufferer from neuritis, especially of the sciatic form. Dr. McArthur's prescription for local application did him more good than any one thing he had used for a number of years. This prescription is: Menthol, 8 grams; oil of gaultheria, 30 grams; creosote, 2 grams.

DR. KUH, in closing the discussion, agreed with Dr. Montgomery that rheumatism and a number of other causes might produce neuritis, Bright's disease among others. With reference to the patient of Dr. Grinker, if there was paresis of the lower extremities, associated with total paralysis of the movements of the eyeballs, Dr. Kuh thought the patient probably did not suffer from a diphtheritic neuritis. Total paralysis of all of the extrinsic muscles of the eyeballs could hardly occur in neuritis.

## MEDICAL SOCIETY OF CALIFORNIA.

*Thirty-second Annual Meeting, held in San Francisco, April 15-18, 1902.*

### President's Address.

At the opening session, the chairman of the committee on arrangements welcomed the members to San Francisco, after which Dr. William J. G. Dawson, St. Helena, president of the society, presented his annual address, reviewing the progress of medical science during the past year. He spoke of the usefulness of state societies and their work, and referred to the new plans of the American Medical Association. In closing he paid a tribute to the members who had died during the last year. Dr. Curtis G. Kenyon, chairman of the committee on revision of constitution and by-laws, made an extended report.

### Hydrotherapy.

At the afternoon session, Dr. George A. Hare, Fresno, read a paper on "Hydrotherapy," and gave a short history of the development of this method, a report of some original experimental work and briefly discussed the physiologic bearings of the subject. He said that in no other branch of medical research had there been so many valuable and beneficial results. The use of heat and cold, simple in themselves, had become a scientific principle in increasing and diminishing blood supply, and he thought that hydrotherapy might well displace venesection. Dr. Frank L. Adams, of Oakland, then read a paper in which he discussed "Hydrotherapy in Typhoid Fever," giving statistics from 1786, when the first successful use of the method was made, up to the present time. The statistics of hospital and private physicians, he said, showed a mortality of from 4 to 7.5 per cent. under hydrotherapy, while, under other forms of treatment, the mortality was as high as from 14 to 26 per cent.

### Hindrances to Care of Insane.

DR. ALDEN M. GARDNER, Belmont, read a paper on the "State Hospital Care and Treatment of Acute and Convalescing Insane," in which he stated that the staffs of physicians in state

hospitals could not accomplish the best results under the existing circumstances of political influence and false economy. At the evening session papers on special topics of ophthalmology, laryngology, rhinology and otology were presented.

The morning session of April 16 was devoted to papers on obstetrics, puerperal diseases and pediatrics; the afternoon session to gynecologic papers.

#### **Bone Grafting; Angiotribe; Appendicitis.**

At the evening session surgery and surgical anatomy were the subjects discussed. Among the papers of interest read in this section were one by Dr. Morton, of the City and County Hospital, on "Bone Grafting," and one by J. Henry Barbat, San Francisco, on "Appendicitis." The latter showed the difficulties that sometimes confuse the diagnostician, reported several cases and contended for immediate operation. This paper, of course, provoked a lively discussion. Dr. Oscar J. Mayer, San Francisco, then read a paper on "The Use of the Angiotribe as Replacing the Ligature in the Routine Work of General Surgery," with an exhibition of his modification of the angiotribe.

#### **Revision of the Constitution.**

At the morning session on April 17, various papers were read. The special committee on the revision of the constitution and by-laws made its final report, which proposed for the association the plan adopted by the American Medical Association. This was approved.

The report of the committee on medical education, submitted by the chairman, Dr. William F. McNutt, San Francisco, called forth a spirited discussion in which charges against a local medical college were vigorously made and the college as vigorously defended by its friends.

DR. GEORGE A. HARE, Fresno, introduced a resolution declaring it the sense of the society that a man, to receive a medical license in California, should have had a good preliminary academic education, but inasmuch as the new law of the state contains this provision, the resolution was not pressed.

The afternoon session was largely devoted to routine business, reports of boards, officers, etc. The following resolutions condemning the action of the mayor of San Francisco in removing the local board of health, and expressing confidence in the board of health recently removed were passed:

WHEREAS, The mayor of the city of San Francisco has seen fit to remove the so-called old board of health, and

WHEREAS, The chief executive of the city has stated that he has determined after a prolonged personal investigation that bubonic plague has never existed in San Francisco, and

WHEREAS, The position is absolutely unsupported by any competent, unprejudiced physician who has made personal examination of suspects or alleged cases of plague before or after death, or who has examined the bacteriologic evidence presented, and is further in direct conflict with the findings of the Federal Government experts and special commission, therefore, be it

Resolved, That the Medical Society of the State of California emphatically condemn this action on the part of the mayor of San Francisco and at the same time endorse the position always maintained by the old board of health in its sanitary defense of the people of the city of San Francisco and of the country at large.

Resolutions were also adopted in favor of the general vaccination law and of the establishment of a vaccine farm.

The election of officers began with tabling the report of the nominating committee, and a spirited election followed, with the following result: President, Dr. Frank B. Carpenter, San Francisco; vice-presidents, Drs. Charles C. Wadsworth, and David A. Hodghead, both of San Francisco; secretary, Dr. George H. Evans, San Francisco; assisting secretaries, Drs. Z. Taylor Malaby and E. M. Bixby, San Francisco; treasurer, Dr. Elmer E. Kelly, San Francisco; board of examiners, Drs. Dudley Tait, San Francisco, David Powell, Marysville, Daniel E. Osborne, St. Helena, Walter S. Thorne, San Francisco, and R. L. Wilbur, San Francisco; board of trustees, Drs. Charles W. Nutting, Etna Mills, Thomas Ross, Sacramento, Frank L. Adams, Oakland, Philip M. Jones, San Francisco, Andrew W. Morton, San Francisco, George L. Cole, Los Angeles, George A. Hare, Fresno, W. S. Fowler, Bakersfield, Curtis G. Kenyon, San Francisco, Julius Rosenstirn, San Francisco, and W. LeMoine Wills, Los Angeles.

Santa Barbara was selected as the meeting place for 1903.

The association was tendered a banquet by the San Francisco County Medical Society, at which about two hundred were present, Dr. John C. Spencer acting as toastmaster.

### **MEDICAL ASSOCIATION OF ALABAMA.**

*Annual Meeting, held in Birmingham, April 15-18, 1902.*

#### **First Session, April 15.**

DR. CUNNINGHAM WILSON, on behalf of the Jefferson County Medical Society and the local physicians, welcomed the visitors to Birmingham. Hon. E. L. Dickey extended a welcome on behalf of the mayor, W. W. Drennen, who was obliged to be absent.

The President, DR. EDWIN L. MARECHAL, Mobile, in his address, gave a brief history of the association. It was organized in 1849 and held annual sessions until 1856, when it ceased to exist until after the Civil war. In 1868, the association was reorganized at Selma. Of those present on that occasion only three are living, namely, Drs. Richard F. Marechal and Jacob Huggins of Alabama, and Dr. T. C. Osborne of Texas. The address concluded with recommendations for the future of the association.

#### **Organization.**

DR. JAMES N. MCCORMACK, secretary of the State Board of Health of Kentucky, and chairman of the Committee on Reorganization of the American Medical Association, was then introduced by the state health officer, Dr. William H. Sanders. The reports of the officers for the previous year were presented.

At the evening session, Hon. J. B. Duke, Lafayette, read a paper on "The Relations of the Medical and Legal Professions" and Dr. Glenn Andrews, Montgomery, a paper on "The Prevention and Spread of Infectious Diseases."

#### **Sleep--The Annual Oration.**

The morning and afternoon sessions of April 16 were devoted to the discussion of papers and in the evening the historian's address was presented by Dr. Samuel W. Welch, Alpine. Dr. J. Huggins, Newberne, then made his report as monitor, and the annual oration by Dr. Edwin B. Ward, Selma, followed. The author discussed sleep, its causes, remote and direct, the reason for sleep and the best conformation of habits to obtain normal sleep. These include exercise in the open air to the point of fatigue, avoidance of heavy and late meals and avoidance of severe mental strain before retiring. He impressed on the audience the danger of the habit of taking drugs to produce sleep, as artificial sleep does not satisfy the body. As the phenomena of sleep point to the readjustment of energies, the habits of life should be so conformed as to secure the necessary amount of normal healthy sleep.

#### **Incurable Conditions Relieved by Surgery.**

One of the most interesting papers of April 17 was by Dr. James T. Jelks of Hot Springs, on "Incurable Conditions Amenable to Surgery: Three Operations Followed by Relief of Cirrhosis of the Liver, Hypertrophy of the Prostate and Bright's Disease." Dr. Jelks asserted that Bright's disease was no longer incurable; many cases have been cured through surgical interference. He specially mentioned the work of Mr. Reginald Harrison of London, and the brilliant results of the New York surgeons.

#### **Failures in Treatment of Morphin Habit.**

DR. GEORGE E. PETTEX, Memphis, Tenn., presented a paper in which he gave some reasons for failures in the treatment of the morphin habit. He asserted that the direct cause of the failure of cures in the past was that the mind was not treated as well as the body. The three methods formerly in universal employment were the sudden withdrawal, the rapid withdrawal and the gradual withdrawal of morphin from patients. He pointed out that in all three of these methods the patient had been left without the habit, but that the mental condition was not treated; he averred that if the mental cure were carried on at the same time the patient would be left strong, not only in body, but also in mind. This paper elicited an animated discussion.

#### **Milk and Infant Mortality.**

During the discussion of the paper of Dr. Thomas D. Park on the "Causation of Infantile Mortality in the State," Dr. John C. LeGrand, Birmingham, said that many dairies tended to enlarge the mortality by furnishing impure or polluted milk for infant food. He urged that stringent laws be passed

whereby dairymen could be more carefully watched, and spoke of the general failure of mothers to sterilize milk before feeding to infants. He then narrated his personal observations on the fatal results following the use of polluted milk as infant food.

#### General Business Session.

The greater part of the session of April 18 was devoted to the reports of the censors, counsellors, correspondents and other officers and revision of the rolls of the county societies. The report of the committee on the Jerome Cochrane monument was also received, which stated that the committee was now ready to receive contributions and asked the active co-operation of all members. Reference was made in the report of the senior censor to a bill now pending before Congress which seeks to change the Marine-Hospital Service. The censor objected to this, but the association decided to refer the matter back to the censors until next meeting. The other recommendations of the senior censor in reference to state laws were adopted.

#### Election of Officers.

The election of officers resulted as follows: President, Dr. Glenn Andrews, Montgomery; vice-president, northern division, Dr. Andrew McA. Stovall, Jasper; orator, Dr. Lewis C. Morris, Birmingham; alternate orator, Dr. George S. Brown, Birmingham; and members of the board of censors, William H. Sanders and Dr. Henry A. Moody, Bailey Springs. Dr. Glenn Andrews, Montgomery, president-elect, resigned as member of the board of censors and William E. B. Davis, Birmingham, was elected to fill the vacancy.

The association adjourned to meet at Talladega next year.

#### Entertainment.

The entertainment provided by the local physicians consisted in a reception by members of the Jefferson County Medical Society at the Hillman Hotel, a luncheon by the local medical society at the Country Club, and a buffet luncheon given by Dr. George Brown.

### UNIVERSITY OF CHICAGO MEDICAL CLUB AND RUSH MEDICAL SOCIETY.

*Joint Meeting, held April 7, 1902.*

Dr. Donaldson in the Chair.

DR. GEORGE SHAMBAUGH read a paper on "Bone Cyst of the Middle Turbinate Body," of which the following is an abstract:

A cyst lined with epithelium and having thin bony walls is occasionally found in the anterior end of the concha media. Such cysts are, as a rule, empty, air-containing cavities, but are occasionally found to be the seat of a mucocele or an empyema.

The cyst represents a greatly enlarged ethmoid cell. The concha media is a part of the ethmoid bone. It represents the median extension of one of the partition-plates of the ethmoid labyrinth, analogous to the unciform process and the bulla ethmoidalis. The bulla is usually the seat of an ethmoid cell and occasionally such a cell is found in the unciform process. In a similar way the base of the concha media is not infrequently the seat of an ethmoid cell. It is the excessive enlargement of such a cell that produces the bone cyst of the concha media or concha bullosa.

The enlargement may, in some cases, be the result of supuration in the cell, the outlet of which has become closed, but, as a rule, such cysts are not associated with any inflammatory discharge, while the opening is usually very large and not easily closed by inflammatory swelling. The enlargement, in most cases, is probably not the result of an inflammation, but represents an anatomic variation, the result of a developmental anomaly. Such variations are common among the other cells of the ethmoid labyrinth, sometimes only two very large cells filling the entire labyrinth; at other times the space being occupied by a great many small cells.

DR. DAVENPORT read a paper on "A Quantitative Study of Variation in Scallops." This paper was read earlier before the American Morphological Society of Chicago and was reported with the report of that organization in *Science*, April 5, 1902.

Both papers were discussed by Dr. Donaldson and Dr. Barker.

### FLORIDA MEDICAL ASSOCIATION.

*Twenty-ninth Annual Meeting, held in Tampa, April 9-11, 1902.*

#### Opening Session.

Dr. George H. Altree, Port Tampa City, called the meeting to order and Mayor F. L. Wing delivered the address of welcome, to which response was made by Dr. J. Harrison Hodges, Gainesville.

The president's address was read to the assembly by Dr. J. D. Fernandez, Jacksonville, in the absence of Dr. A. Judson Wakefield, Jacksonville. The remainder of the session was taken up by the reports of committees and of the county medical societies. A reception was tendered the visiting members by Dr. Louis A. Bize, Tampa.

#### Charges Against Dr. Porter Unfounded.

The charges preferred against Dr. Joseph Y. Porter, Key West, by the Hillsboro Medical Society, that he had quarantined against Tampa for yellow fever, and that on a similar occasion he had not quarantined another place, but had concealed a case, had been referred to a committee, which reported that the matter had been thoroughly investigated and found to be absolutely without foundation. The report was adopted by the association.

#### Annual Banquet.

The annual banquet was held at the Café Poleca, at which Dr. Edward N. Liell, Jacksonville, delivered an address on the "Progress of Medicine in Florida," and Dr. J. D. Fernandez, Jacksonville, responded to the toast "The Florida Medical Association."

#### Officers Elected.

The election of officers resulted as follows: President, Dr. J. Harris Pierpont, Pensacola; vice-presidents, Drs. Edward N. Liell, Jacksonville, and John MacDiarmid, De Land.

St. Augustine, April 8, 1903, will be the place and date of the next session.

### MISSISSIPPI STATE MEDICAL ASSOCIATION.

*Thirty-fifth Annual Meeting, held at Jackson, April 16, 1902.*

The President, Dr. James M. Buchanan, Meridian, in the Chair.

#### Opening Session.

The association was welcomed to the city by the Hon. J. B. Sterling and response was made for the association by Dr. Julius Crisler, Jr., Jackson. After the usual reports of the committees, a resolution was adopted appointing a committee to look into the advisability of reorganization of the state and county societies on the lines suggested by the American Medical Association. The following committee was accordingly appointed: Drs. Joel C. Hall, Frank Jones, William Payne, J. Augustus Crisler, and H. L. Sutherland.

#### Hygiene and Sanitation.

DR. WILLIAM M. KRATZ, Memphis, Tenn., then read a paper on "X-Rays in Medicine and Surgery." Dr. Hyman M. Folkes, Biloxi, made a report of "Infant Mortality, Its Cause and Prevention." Dr. Harris A. Gant, Jackson, president of the State Board of Health, presented a paper on "Hygiene and Sanitation." He made a number of valuable suggestions, among which were isolation in tuberculous disease; the establishment of a state tuberculosis sanatorium on the cottage plan for the poor; restrictions of spreading of disease by proper hygienic precautions, among which he mentions the disinfection of telephone receivers, and the aseptic management of infectious fevers and pneumonia. In conclusion he stated that Mississippi was in need of thorough sanitary overhauling and urged the physicians and public generally to unite in the attainment of this object.

#### Department of Public Health.

The second day's session resolved itself into a meeting of the Department of Public Health, of which Dr. Carroll Kendrick, Kendrick, was made president, and Dr. K. P. Perkins, Batesville, secretary. A resolution was passed favoring a bill for the collection of vital and mortuary statistics and the appoint-

ment of a physician from each county society to co-operate with the county health officer.

The regular work of the association was then resumed and a number of interesting papers read and discussed.

#### Insanity and Care of Insane.

The president, in his annual address, spoke of the care of the insane and showed the evolution of the present method of treating insanity, and the growth of all rational theories from that of demoniacal possession to the theory that all insanity is the result of physical derangement, which may in many cases be discovered and successfully treated. As much can be accomplished through moral agencies as by medicines, and to this end patients in state hospitals for the insane should have as much home-like environment as possible. The asylum should be placed on a purely medical basis. Superintendents should have secretaries to relieve them of much of the excessive non-medical work. The assistant physicians should be progressive men and should devote their time to study of the patients and to pathologic work. The internes should record cases, copy notes, etc., and at least one physician should devote his time to original investigation. He further urges the establishment of training schools for nurses of the insane.

#### Election of Officers.

The association adjourned after electing the following officers: Dr. H. L. Sutherland, Rosedale, president; Drs. J. H. Roby and Joseph T. B. Berry, Brandon, vice-presidents; Dr. Clifford H. Trotter, Northfield, secretary; Dr. Benjamin L. Culley, Jackson, assistant secretary; Dr. David S. Humphreys, Greenwood, corresponding secretary; Dr. John F. Hunter, Jackson, treasurer; Drs. W. M. Paine, Aberdeen, K. P. Perkins, Batesville, W. H. Scudder, Mayersville, Charles D. Mitchell, Pontotuc, John R. Tackett, Meridian, Hyman M. Folkes, Biloxi, and Louis D. Dickerson, McComb City, members of executive committee; Dr. Joel C. Hall, Anguilla, delegate to the American Medical Association, and Dr. W. M. Paine, Aberdeen, alternate. Greenville was selected as the place of next meeting.

#### OMAHA (NEB.) MEDICAL SOCIETY.

*Regular Meeting, held April 8, 1902.*

President, Dr. F. E. Coulter, in the Chair.

#### Floating Kidney.

Dr. A. F. JONAS, in presenting this subject, said that the furor for fixation of the kidney was now as great as had been that for the removal of various organs. He said that the normal kidney floats and gave a résumé of the anatomy, illustrating it with colored diagrams. No kidney is fixed, every one is movable. It is purely arbitrary to say when this movement is abnormal, because there is no standard of normality. The abdominal organs act as a source of support to the kidney; when the liver and the stomach are displaced there is ptosis of all the abdominal organs, often including the kidney.

Dr. Jonas exhibited a very unusual specimen, a sacculated and tubercular kidney with five divisions. It was found in the pelvis and was about nine inches long and weighed about four pounds. The patient suffered no pain. Dr. Jonas then gave a résumé of the etiology and symptomatology of floating kidney.

He emphasized the fact that nephropexy will not furnish relief to those cases in which there is general splanchnoptosis. One must be very cautious in promising relief to such cases. The low abdominal bandage alone will afford the greatest amount of relief in these cases. All bandages designed to keep in place a floating kidney fail in their purpose. In operative procedures, the suggestion of Edebohl that the decortication should be extensive and that the lumbar muscles should be split, not cut, and the sutures passed through the capsule and the muscles, and the muscles then brought together has seemed to him of the greatest possible value. He now brings the decorticated part close up to the fascia of the quadratus lumborum muscle and there firmly attaches it. Another improvement of equal value is the actual delivery of the kidney through the lumbar incision in every case where it is possible, and it is possible in all cases

except those few in which the renal vessels are abnormally short. The diagram of a bipolar kidney furnished the best possible illustration of the wisdom of delivery of the kidney in all cases where possible. In his first operation upon this case, he had brought the kidney up to the incision, but not out of it, had inspected the presenting surface which seemed to be entirely normal and finished the operation. The patient returned in a short time with all conditions as bad as ever. He again operated, this time delivering the kidney and finding it of the bipolar variety, which explained his failure. He decorticated both poles of the kidney and sutured them firmly with most happy results.

#### MEDICAL ASSOCIATION OF GEORGIA.

*Fifty-third Annual Session, held in Savannah, April 16-18, 1902.*

#### General Business Sessions.

The addresses of welcome were made by Hon S. B. Adams and Hon. Walter G. Charlton, Dr. Virgil L. Hardon, Atlanta, responding for the visiting members. The rest of the morning session was devoted to the reports of committees and the reading of papers. In the evening a smoker was given to the delegates at the Savannah Yacht Club.

The second day's session consisted of the reports of the secretary and treasurer and various papers, notable among which were those by Dr. Ludwig Amster, Atlanta, "On Medical Aspects of Life Insurance"; by Drs. Theodore E. Oertel and Eugene E. Murphey, Augusta, on "A Case of Diabetes Mellitus, with Autopsy"; by Dr. Elmore C. Thrash, Oakland, on "Reasons Why We Should Have a State Board of Health"; and by Dr. William P. Williams, Blackshear, on "Preventive Medicine."

The report of the committee on necrology paid fitting tributes to eleven active and honorary members of the society, who had died since the last annual convention.

The chairman of the committee on new members, Dr. Willis F. West Moreland, Atlanta, reported that since the establishment of this committee four years before, the membership had increased from 125 to more than 700.

#### Election of Officers.

The election of officers resulted as follows: President, Dr. Charles Hicks, Dublin; vice-presidents, Drs. Joseph A. Guinn, Conyers and Willet W. Binion, Benevolence; Dr. Alpheus B. Simmons, Savannah, was elected a member of the board of censors, and Drs. Floyd W. McKee, Atlanta, and James B. Morgan, Augusta, were elected delegates to the American Medical Association. Columbus was unanimously accepted as the next place of meeting, for April 16, 1903.

In the afternoon the members enjoyed an oyster roast at Tybee Island.

## Therapeutics.

#### Glycero-Phosphates.

Glycerino-phosphoric acid, according to A. C. Prentice, in *Med. Rev. of Reviews*, is chemically the glycerin ester of phosphoric acid. The neutral salts are most frequently used, are directly assimilable and have a remarkable effect upon nutrition, since the acid represents, chemically, exactly that form in which phosphorus is taken up into the human system. The following is the physiologic action: 1. It accelerates chiefly the nitrogenous exchanges and favors the assimilation of albuminoid substances, increasing the excretion of nitrogen. 2. It does not greatly influence the formation of uric acid, but the increase in the nitrogenous elimination often lowers the proportion of uric acid to urea. 3. It acts on the sulphur metabolism, increasing the oxidation of the broken-up sulphur products. 4. It has no marked effect on intestinal fermentations. 5. It increases elimination of sodium chlorid and hence this corresponds with the clinical fact of improved appetite. 6. It favors the assimilation of the phosphates in the food by the nervous system, exerting an economic action by saving up

combined sulphur. 7. It increases the change of osseous substance without materially influencing that of phosphorus. He recommends it in the treatment of rachitis, phosphaturia, gout, anemia, chlorosis and in general functional and asthenic states of the nervous system. In the anemias, the iron preparation of the glyceo-phosphato acts pre-eminently as a blood builder.

#### Dysentery Treated with Peroxid of Hydrogen.

Rocaz, as noted in *Med. Rev. of Reviews*, states that he has derived great benefit from the use of this agent in treatment of dysentery in ten cases ranging in age from two to twelve years. Lavage of the rectum with the hydrogen peroxid was practiced two or three times a day; the effect was speedy and marked. Within two or three days the character of the stools was materially changed; blood and mucus disappeared, the stools became less frequent and the sphincter regained its tonicity. It is necessary to continue medication some days after subsidence of the symptoms.

#### Gastropathies of Cardiac Origin.

Cardiac lesions are often complicated by gastric troubles of more or less gravity, which, as stated by Vallentin in *Med. Rev. of Reviews*, appear in about 20 per cent. of the cases. According to his statement these disturbances appear in order of frequency in mitral, aortic, myocarditic and pericarditic lesions. In the majority of these cases the symptoms are anorexia, obstinate vomiting and sometimes hematemesis; which in turn may aggravate a heart lesion. A milk diet, under such circumstances, should be resorted to and the following bitter stomachic and tonic administered:

|    |                                |      |    |
|----|--------------------------------|------|----|
| R. | Tinct. nucis vom. ....         | 3i   | 4  |
|    | Tinct. gentianæ ....           | 3ii  | 8  |
|    | Tinct. rhei co. ....           |      |    |
|    | Aq. laurocerasi, āā. ....      | 3v   | 20 |
|    | Aq. menth. pip. q. s. ad. .... | 3iii | 90 |

M. Sig.: One teaspoonful in weak tea before eating. During the gastralgic attack the following preparation is of benefit:

|    |                          |          |    |
|----|--------------------------|----------|----|
| R. | Cocainæ hydrochlor. .... | gr. viii | 50 |
|    | Aq. aurantii ....        | 3i       | 30 |
|    | Aq. chloroformi ....     | 3iiss    | 75 |
|    | Aq. destil. ....         | 3iiss    | 45 |

M. Sig.: One to three teaspoonfuls in soup at the beginning of the attack.

#### Pain Previous to Menstruation.

The *New York Med. Jour.* recommends the following in treatment of premenstrual pain:

|    |                        |         |     |
|----|------------------------|---------|-----|
| R. | Codeinæ ..             | gr. 3/4 | 105 |
|    | Chloral hyd.           |         |     |
|    | Ammon. brom., āā. .... | gr. xii | 75  |
|    | Aq. camphorate ....    | 3i      | 30  |

M. Sig.: To be taken at one dose at bedtime.

#### Eczema.

|    |                          |         |    |
|----|--------------------------|---------|----|
| R. | Cocainæ hydrochlor. .... | gr. iii | 20 |
|    | Atropinæ sulphatis ....  | gr. i   | 66 |
|    | Morph. sulphatis. ....   | gr. ii  | 12 |
|    | Ung. acidi carbol. ....  | 3i      | 30 |

M. Sig.: Apply locally once or twice a day; or:

|    |                         |        |    |
|----|-------------------------|--------|----|
| R. | Bismuthi subnit. ....   | 5iv    | 15 |
|    | Zinci oxidi ....        | 3i     | 30 |
|    | Acidi carbol. liq. .... | m. xxx | 2  |
|    | Vaselini albi ....      | 3ii    | 60 |

M. Sig.: Apply locally night and morning.

#### Dandruff.

The following has been recommended in treatment of dandruff, first cleansing the scalp thoroughly with tar soap and carefully drying the hair:

|    |                                 |       |    |
|----|---------------------------------|-------|----|
| R. | Sulphuris precip. ....          | 3iiss | 6  |
|    | Lanolini ....                   | 3i    | 4  |
|    | Adipis benzoatis q. s. ad. .... | 3i    | 30 |

M. Sig.: Apply thoroughly to the scalp by rubbing in well. The same procedure may be repeated every four or five days.

#### Pneumonia.

E. D. Chesebro, as stated in *Ther. Monthly*, emphasizes the following points in the management of pneumonia: 1. Carefully regulate the diet, guard against constipation and insist on the

liberal use of pure water. 2. Early in the course of the disease, employ counter-irritants, particularly in the bronchopneumonia of children. 3. Relieve distressing cough by inhalations and, if necessary, by the use of opium or its derivatives. 4. Relieve pleuritic pain by the intermittent use of hot or ice poultices or by the subcutaneous use of morphin. 5. Reduce temperature, if necessary, by bathing. 6. Stimulate the heart with strychnia and, in selected cases, with alcohol, digitalis and normal salt solution. It is possible that venesection, which may be followed immediately by the injection of normal salt solution, is indicated in certain cases of engorged heart and if boldly done may be the instrument in saving life. 7. Employ large and frequently repeated doses of antipneumococcus serum in desperate cases, particularly in those with a tendency to extension of the inflammatory process.

#### Scabies.

The following is Herxheimer's treatment of scabies:

|    |                             |       |    |
|----|-----------------------------|-------|----|
| R. | Birch tar                   |       |    |
|    | Sulphuris precip., āā. .... | 3iiss | 10 |
|    | Tinct. saponis viridis      |       |    |
|    | Vaselini, āā. ....          | 3v    | 20 |

M. Ft. unguentum. Sig.: Apply locally, covering the affected region once a day for three or four days following the last application by a warm bath; or:

|    |                         |     |    |
|----|-------------------------|-----|----|
| R. | Balsami Peruviana       |     |    |
|    | Liq. storacis, āā. .... | 3iv | 15 |

M. Sig.: Apply once daily for three days and then remove with alcohol. Either method is said to be destructive to the acarus.

#### Synovitis.

The following is recommended in treatment of synovitis, from any cause:

|    |                        |     |     |
|----|------------------------|-----|-----|
| R. | Chloral hydratis. .... | 3iv | 15  |
|    | Acidi carbolici ....   | 5ss | 2   |
|    | Aque q. s. ad. ....    | Oi  | 480 |

M. Sig.: Apply, as hot as possible, upon layers of lint, changed every hour and covered with oil silk.

#### Preventive Treatment in Diphtheritic and Scarlatinal Angina.

L. Kürt, in *Ther. Monthly*, states that he endeavors to stimulate the salivary glands by means of sugar, candy or fruits. By these means he has attained remarkable results. The hypersecreted saliva is swallowed and is thus brought in contact with the pharynx. He recommends even awakening the patient at night every half hour to give a piece of sugar in order to stimulate the salivary secretion. He states, by this method, a beginning angina can be successfully combated and, even in pronounced cases, marked improvement will become manifest within two or three days. In those cases, thirty in all, in which this method has been employed by him, recovery followed within a week. Laryngeal complications were never observed, and in diphtheria, antitoxin was not used in conjunction with the foregoing treatment.

As to the diet in scarlet fever N. S. Davis, in "The Sys. of Phys. Ther.," recommends, during the few days of fever, cool drinks—water, lemonade and seltzer in large quantities. The food must be liquid. Milk is the best, which can be varied by gruels, oranges, baked apples and stewed prunes. If the throat is in such a condition as to prevent swallowing, rectal alimentation must be employed. Care should be taken that enough fluid be administered per rectum to maintain good elimination by the kidneys.

Ice cream can often be swallowed with comfort when fluids give pain. As nephritis occurs more frequently in scarlet fever than in any other eruptive disease, such a diet should be prescribed as will avert it. It is said by Jacoud that scarlatinal nephritis can always be avoided by a rigorous milk diet if persevered in until after the third week. The smallest possible amount of albuminous and nitrogenous diet should be given in order to relieve the kidneys of all the work possible. After the third week, a greater variety of nourishment may be given, such as fish, creamed codfish, oysters or clam broth, squab and breast of chicken. In case acute inflammation of

the kidneys develops, the regimen must be that of nephritis rather than of scarlet fever.

## Medicolegal.

**State Board of Health and Compulsory Vaccination.**—The principal question before the Supreme Court of Kansas, in the case of *Osborn vs. Russell*, was whether the authority granted to the State Board of Health by Section 4 of Chapter 129 of the Laws of Kansas of 1885 vested in the board power to make a regulation that "no person until after being successfully vaccinated shall be admitted into public or private schools." That act provided that "the State Board of Health shall supervise the health interests of the people of the state," and "the State Board of Health shall adopt and publish such rules and order of business as may be necessary to make this act effective." By recent legislation the powers of the State Board of Health have been greatly extended, and the court does not intend anything said in this case as an intimation with reference to the present scope of such powers. But what it holds in this case is that, under the provisions quoted, the State Board of Health had no power or authority to adopt such a regulation, and that its order did not invest a board of education with the authority to deny admission to the public schools of unvaccinated pupils. The court says that the question was not before it, but that it is assumed that the legislature has authority to enact such laws as are requisite for the preservation of health, and to prevent infection from contagious diseases, and it may well be that such power can be delegated. The courts have usually sustained specific regulations intended to prevent the further extension of an epidemic, or to prevent the same when danger thereof appears imminent, and authority given to cities to establish quarantine in such cases has been uniformly upheld. Lastly, the statute requiring the maintenance of a system of free common schools in each city of the second class in the state, "which shall be free to all children residing in such city between the ages" specified therein, the court holds that, in the absence of a lawful regulation prescribed or authorized by the legislature, a board of education of a city of the second class has no authority, at a time when the disease of smallpox does not exist in or near such city, to deny a child of school age, resident therein, admission into the public schools because such child has not been vaccinated.

**Limiting Privilege to Physicians of State.**—Section 3649 of the General Statutes of Colorado provides: "A physician or surgeon duly authorized to practice his profession under the laws of this state, shall not without the consent of his patient be examined as to any information acquired in attending the patient, which was necessary to enable him to prescribe or act for the patient." The question was raised, in *Head Camp, Pacific Jurisdiction, Woodmen of the World vs. Loehner*, as to the effect to be given the words, "duly authorized to practice his profession under the laws of this state." It was urged that the words should not be construed in the sense of limiting or restricting the class to which the statutory privilege applied, but rather in accord with what it was contended was the policy and intent of the enactment as expressed in the preamble, which recites that "there are particular relations in which it is the policy of the law to encourage confidence, and to preserve it inviolate," etc. In other words, it was insisted that the words in question should be entirely eliminated from the statute, thereby making it apply to all physicians, authorized or unauthorized to practice, licensed or unlicensed. But the Court of Appeals of Colorado does not see how, under any authority or rule of construction, a court would be permitted to pursue that course in this case, where it was conceded that the witness, a physician resident in New Jersey, was not authorized to practice his profession under the laws of Colorado. It says that the provisions of the statute as it now reads are clear, intelligible, and easily understood, can not be said to be in any sense unreasonable or absurd, are subversive of no legal private rights, and are not inconsistent with themselves or with any other law. Under such circumstances, however fully the court

might agree with counsel that they should be extended and broadened, the courts are without power in that regard. The remedy is with the legislature alone. That no state has a similar law—one containing the restrictive words under consideration—the court says, is not an argument that they were improvidently used, and that the courts of Colorado should disregard them. Rather, if the fact has any bearing upon the question at all, it would tend to support the contention that they were inserted advisedly, and for a specific purpose. The statute was enacted in 1883. This was the legislative session immediately succeeding the one (1881) in which the legislature first adopted the law providing regulations for the practice of medicine in Colorado, and prohibiting it without a party having been first authorized under its provisions. It may well be that the legislature placed these words in the later statute with the deliberate purpose of carrying out and aiding the policy which it had adopted in the prior one. Wherefore the court holds that the physician referred to was not rendered incompetent to testify as a witness because of this statute.

**Skill Required in Specialist—Inadmissible Evidence.**—The Appellate Court of Indiana says, in the malpractice case of *Baker vs. Hancock*, that the measure of the duty of a general practitioner is that he does not undertake absolutely to cure, but is bound to possess and exercise the average degree of skill possessed and exercised by members of the profession practicing in similar localities, and having regard to the advanced state of the profession at the time of treatment. A specialist, as the term was here used, is understood to mean a physician or surgeon who applies himself to the study and practice of some particular branch of his profession. Scientific investigation and research have been extended and prosecuted so persistently and learnedly that the person affected by many forms of disease is of necessity compelled to seek the aid of a specialist, in order to secure the results thereof. The local doctor, in many instances, himself suggests and selects the specialist whose learning and industry have given him a knowledge in the particular line which the general practitioner, in rural communities especially, has neither time nor opportunity to acquire. Being employed because of his peculiar learning and skill in the specialty practiced by him, it follows that his duty to the patient can not be measured by the average skill of general practitioners. If he possessed no greater skill in the line of his specialty than the average physician, there would be no reason for his employment; possessing such additional skill, it becomes his duty to give his patient the benefit of it. So the court holds that the party sued, if he held himself out as a specialist in the treatment of cancer, was bound to bring to the discharge of his duty to patients employing him as a specialist that degree of skill and knowledge which is ordinarily possessed by physicians who devote special attention and study to the disease, its diagnosis and treatment, having regard to the present state of scientific knowledge. This was the degree of skill which, by holding himself out as a specialist, he represented himself to have; and, the court adds, it did not lie with him to assert, after securing employment and compensation on that basis, that his representation was not true. The main fact upon which liability was made to depend in this case being whether or not the party sued negligently failed to diagnose the disease, and so failing negligently made a local application, because of which the nose of the party suing was eaten off, the court holds that the latter could not introduce witnesses to prove that the party sued had pronounced certain ailments of theirs cancers, and sought to treat, and in one case did treat, them for such disease, while the sores, so diagnosed as cancers, got well by the application of simple remedies. There being no connection between the offered proof and the diagnosis and treatment given the party suing, the court holds that it was, therefore, collateral and inadmissible. Likewise, it holds inadmissible evidence introduced by the party sued, relating to his treatment of various other persons, and entirely disconnected from the treatment of the party suing. It says that it could make no difference as regards the admissibility of such evidence whether the result was good or bad. It was inadmissible in either event.

1. **Pneumonia.**—Burt's essay summarizes as follows: "Pneumonia is an acute, self-limited, systemic infection, whereof the concomitants, though various, are chiefly pulmonary; it is endemic, occasionally pandemic, in many countries, and it occurs everywhere sporadically; regarding the lung tissue, the affection seems more in the nature of an exudation than an inflammation; the frequency of detection of the diplococcus in living blood in pneumonia suggests that by improved technic it will be found, like the plasmodium in malaria, invariably; infection of the heart muscles with resulting

degeneration has more to do with heart failure than mechanic obstruction; the exact significance of pathologic leucocytosis requires further elucidation; preëxisting fertility, as to the condition, determines the degree of infection, rather than the number of microbes, which are in quality unchangeable; although neglect of personal hygiene and of sanitation predisposes to pneumonia, unqualified good health, on the other hand, is a protection therefrom."

2. **Marrow and Spleen Cells.**—Williams finds that the marrow cells are basophilic, a fact which has hitherto been unnoticed. He has tested this by reagents and satisfied himself that the marrow cells are identical with the so-called large lymphocytes of the blood whose origin has been hitherto in dispute. The large lymphocyte is the true myelocyte of the blood. The oxyphile myelocytes of Cornil and Ehrlich, found only in diseased blood, are probably degenerated forms. He agrees with the statement of Clarkson that the marrow cells are capable of movement and finds that they are in all probability the progenitors of the multinuclear leucocytes, a view also held by Boehm and von Davidoff. The spleen cells are predominantly red corpuscles. White corpuscles are far less common in the spleen than in the marrow. The obvious conclusion from his study is that red corpuscles are elaborated by the spleen. The spleen seems to have a less important tendency in the formation of leucocytes than the marrow and lymph glands and very little share in the production of multinuclears. It probably does contribute a few of the large uninuclear leucocytes designated by Virchow as splenocytes. This can, however, be practically of little value as they can not well be distinguished from the true basophilic myelocytes.

4. **Bisection of the Uterus.**—The method of bisecting recommended by Richardson is described by him as follows: Instead of making the incision in the median line, it is made on either side, beginning near the horn of the uterus, and carried down through the tissues of the walls of the uterus and cervix; so when completed one section contains practically the whole body of the uterus with its cavity, and the other only a narrow strip of the wall. A little practice will teach one to keep within the walls of the uterus. The hemorrhage is a trifle more profuse from the narrow strip than when divided in equal parts, but this is of minor importance. It will be seen at once that this method of bisection allows all the advantages of median bisection, but admits of no danger of infection from the uterine cavity, the heretofore principal objection of its opponents.

7. **Pneumonia.**—Eichberg favors the use of anti-pneumococcal serum in pneumonia and shows by statistics of various hospitals that the mortality is rather high in the ordinary treatment and certainly well above that reported with serum treatment by Pane and other authorities. He considers the method harmless and thinks that the large amount used should not weigh against it, as it causes only a temporary inconvenience. He reports several cases, and calls attention to the relief of cough and expectoration soon after the administration of serum. The process of resolution is apparently accomplished without any liquefaction, for no moist sounds were heard. Efforts to make blood counts failed on account of the prompt clotting of the blood in the counters.

8. **Blood Examinations.**—Baldy's article is a polemic one in reply to that of Willson, who criticised his views. He says that Willson's article really admits what he claims—that blood examinations are of scientific use, they are often of no practical value and they may misguide the surgeon.

10. **Summer Diarrhea.**—Kerley gives his experience with summer diarrhea in out-patients and has come to believe that its large mortality in infants is avoidable. Nevertheless, every case of summer diarrhea is dangerous and should be treated vigorously no matter what the initial symptoms may be. Acute streptococcal or colon bacillus infection plays, he thinks, no large part in the beginning symptoms. A case of so-called dyspeptic diarrhea, with continued milk feeding, will soon become a virulent infection. The first thing to be done is to stop the milk and for a substitute he uses barley or rice water with chicken, beef or mutton broths in small quantities to prevent too much laxative effect. The white of egg mixture

he has discontinued, because it does not appear to digest readily in many children and forms as good a putrefactive culture medium as milk. Fever is always present and he quotes Hutchinson as stating that the leading characteristic of fever is increased destruction of nitrogenous tissues, but the apparent indication that we must supply proteids is not correct as it is impossible to bring about a condition of nitrogenous equilibrium in acute fevers in this way and it increases the strain upon the kidneys—thus aggravating the condition. The loss of fluid by the intestines in summer diarrhea makes the urine more concentrated, hence, more toxic to the kidney structure, and, as Hutchinson says, we must see that proteid spacers are more abundantly represented in the diet as well as a liberal supply of carbohydrates. The by-products of these are thrown off through the lungs as carbon dioxide and thus the body is sustained and the kidneys rested. The condition of the intestinal contents is changed from putrefaction to fermentation and is less favorable to the growth of dangerous pathogenic organisms. He finds that dextrinized gruels have a useful field in the diets for summer diarrhea. The patient is to be kept in the largest room and, if febrile, sponged with water at 80 F. for fifteen minutes several times a day. The resumption of the milk diet should be gradual while the patient convalesces. For drugs Kerley uses calomel in cases of vomiting, giving 1/20 to 1/10 of a grain by hypodermic injection. Castor oil is given in acute septic cases with infrequent stools and without stomach involvement, in which a prompt washing out of the small intestine is desired. In all cases, bismuth in large doses was given every one or two of the waking hours, but to be serviceable it must produce black stools. In a few cases it goes through the bowel unchanged and exerts no influence. He credits this to absence of sulphuretted hydrogen in the intestine, due doubtless to the absence of pancreatic digestion. In such cases he gives a grain of precipitated sulphur with each dose of bismuth. Opium is indicated where there is severe pain or tenesmus, and very frequent stools. Four or five stools a day he considers not too many; simply maintain proper drainage. When the case is one of intestinal infection, with infrequent foul discharges or none at all, active laxatives constitute the only medication. Many children are sacrificed because of the notion that the diarrhea must be completely stopped. Irrigation of the colon has been overdone. It does not follow that, because a child has diarrhea, irrigation should be used. Ten or twelve loose, watery discharges wash out sufficiently without requiring anything further. Patients that are benefited by irrigation are those that have a moderate number of green mucous stools with or without blood. Cases to be irrigated are those in which there is something to be washed away. He usually employs for such cases normal salt solution, or, if there is blood, a 1 per cent. solution of tannic acid, although he questions its special value. It is applied lukewarm, and, if there is a high fever, he uses it at 60 or 70 F.; in the very weak, with subnormal temperature and marked prostration, the solution is used at 110 F. The method of irrigation is described. As regards the medical management, a great deal rests with the proper education of the mother and prophylaxis. The child should be properly fed and great care should be taken to prevent infection of the bottle and nipple; the mother should be told to wash her hands with soap and water before preparing the baby's food. Municipalities should establish milk laboratories and stations where sterilized milk and cereal gruels should be furnished free to the poor, and at small cost to others. The educational program should be thoroughly carried out.

**11. Joint Disease of Children.**—The different forms of joint disease occurring in children are reviewed for diagnosis by Myers, who finds the complete blood examination of considerable value in determining whether abscess exists or not. The treatment of the different types is also mentioned, including the mechanical treatment. We should act not only for the immediate relief of the symptoms, but also with regard to the ultimate results. For instance, early incision only can save the head of the femur in acute epiphysitis. If this is not saved, the ultimate result resembles congenital dislocation, but

is worse because reposition is impossible. Sometimes, however, dislocation does not occur and in these cases a very useful limb results. If the medullary cavity of a long bone is to be cleaned out, care should be taken not to destroy the living shell or to fracture it. The diaphysis should not be removed entire in a case of acute necrosis, but should rather be left as a splint until the bone forms. Myers says not to operate too quickly and completely in dactylitis, if we wish always to save the shape of the finger. Osteomyelitis about the knee-joint is very apt to be followed by partial subluxation of the joint or atrophy of one condyle. Of course, the proper use of splints will do much good in preventing deformities. As regards medical treatment, he speaks particularly of good diet, hygienic surroundings, etc.

**12. Typhoid Fever.**—Doane recalls the statement by Trouseau that unilateral deafness occurring in typhoid is of grave import, while a similar bilateral condition is a favorable sign. He has found this a valuable point in the prognosis. The cause of the condition is unexplainable to him, but he offers the fact to the profession as of some interest.

**15. Pneumonia.**—The recapitulation and substance of Burt's article is given as follows: "Pneumonia primarily owes its shortness and self-limitation to the perishability of its micro-parasite; the type of the disease depends upon the condition of the individual; pneumonia simply as pneumonia requires no interference; diplococci thrive best at the normal human temperature; fever inhibits the growth of the parasite and is therefore beneficial; high fever indicates extensive infection, meantime varying degrees of reactive ability; low fever either inability to react or else moderate infection; specific medication is unnecessary in pneumonia, if not pernicious; it is imperative to disinfect dejecta and expectoration; aconite and its congeners are injurious; bleeding is seldom required; opium, checking renal activity, in large doses is contra-indicated; in old persons opium is exceedingly dangerous; oxygen is useful, but not indispensable; alcohol is valuable as food, and it conserves energy; strychnia, ammonia, alcohol and nitroglycerin in large doses, as stimulants, should be reserved for emergencies; subcutaneous infusion of a physiologic saline solution is invaluable for renal elimination of poisonous accumulations; last, though not least, specific remedies at best are but make-shifts, prevention of infection is the desideratum."

**16. Bright's Disease.**—Edebohls argues for his priority over A. Rose in the matter of surgical treatment of chronic Bright's disease, and reviews the literature in support of his opinions.

**17. Breast Milk.**—The point made by Southworth is the importance of instructing mothers in regard to the value of their diet and hygiene so as to be able to successfully nurse their infants. His directions are simple, such, for example, as the addition to plain sensible food of cornmeal gruels and the disuse of coffee and tea and substitution of cocoa. He insists on the importance of mothers nursing their children and thinks there would be little difficulty if they would sacrifice social dissipation and unsuitable food for the sake of the child.

**19. The Ambulant Consumptive.**—This article deals with the importance of care as to the sputum, cough, etc., on the part of the consumptives. The author takes what might be considered rather extreme views. The greatest danger to the public in his opinion is because consumptives do not die quick enough. He thinks it would be a blessing if the disease were a rapid one and carried them off quickly. A large part of his paper is devoted to the description of portable cuspidors. He speaks positively in regard to spitting, saying it is a crime to spit on the floor or ground and should be treated as such, and all receptacles and public cuspidors should be done away with. Tobacco chewers deserve no consideration, and we have met all the needs of the consumptive when we give him a practical, easy and efficient way to handle the sputum.

**23. The Koch-Weeks Bacillus.**—From these cases here reported Shumway deduces the following conclusions: 1. The Koch-Weeks bacillus conjunctivitis is apparently becoming more common in Philadelphia than has been hitherto observed. 2. It may present itself in a particularly severe form, and be complicated by phlyctenules and even by corneal ulceration.

3. These cases are especially contagious, and extra precautions should be taken to prevent their spreading, particularly among school children. 4. As a rule, they are controlled by the use of mild astringent lotions and applications of 2 per cent. solutions of nitrate of silver. We have not tried protargol, but equally good results have been obtained by other observers, when the solutions used have been of sufficient strength, viz., 10 to 20 per cent.

**25. Prostatic Hypertrophy.**—Guiteras notices the diagnosis, indications for operation, choice of operation and indications for each. He rather favors prostatotomy or the Bottini method, but shows that prostatectomy, according to one or other of the methods used, has its advantages in many cases. His conclusions are: 1. That the general practitioner should be educated to palpate the prostate and to use the other simple means of diagnosis employed in determining the shape and size of the organ. In default of previous training in rectal palpation, he should at every opportunity familiarize himself with the feel of a normal prostate, and should thus educate his touch for prostatic diagnosis. 2. That the prostate corresponds pathologically in the male to the uterus in the female, and that its examination is just as important as uterine palpation, in which the general practitioner is, as a rule, far more expert. 3. That in prostatics the care of the bladder before operation is a prime factor. The importance of training such persons to observe the minutiae of catheter life, of making the kidneys as active as possible, and of rendering the urine as nearly normal as possible before prostatic operations, can not be overestimated. 4. That every prostatic operation should be preceded by a thorough general examination, including an examination of the heart, the arteries, the urine, the bladder (for possible presence of stone or tumor) and of the urethra (for possible presence of a stricture), as well as by palpation of the kidneys. 5. That the statistics of the results of prostatic operations demonstrate that the successful cases belong most frequently to the class having a small amount of residual urine and a moderate prostatic enlargement. An early diagnosis is, therefore, of paramount importance. 6. That the choice of the operation must be based upon the lines drawn here, according to the age, the resisting power of the patient, and the size and shape of the prostate, with special reference to the seat and extent of the hypertrophy, as well as the condition of the kidneys and bladder. 7. That in the conduct of prostatotomy as well as prostatectomy the prime object is to avoid so far as possible the occurrence of shock and to prevent the congestion of the kidneys by proper precautions during and by proper treatment after the operation.

**26. The Bottini Operation.**—The contra-indications for the Bottini operation are by Schmidt not considered so general as some have held. He says that good results have been obtained in some cases under conditions against which we have been specially warned, such as nephritis, morbid conditions of the kidneys, ureters and bladder, general arteriosclerosis and pyemia. Still, we must take these things into consideration. He emphasizes, however, that if thorough cystoscopic examination can not be made, it is best not to undertake the operation. He thinks the objection that cicatricial contraction results is not warranted by facts—provided that the method be correct. Poor technique is responsible for a large number of complications. He would not, however, be understood to declare the Bottini operation an easy one or that anyone can perform it. It is on account of such ideas that we hear of bad results. We should always be able to recognize any accident that may occur or complications that may arise subsequently and it must not be forgotten that the after-treatment plays an important part in the results. The conclusions which he draws are that good results of operation will depend: 1. On careful selection of cases. 2. On proper technique of the operation and proper after-care. 3. On immediate correction of errors or mishaps.

**27. Gonorrheal Prostatectomy.**—Frank holds that adequate therapeutic measures limit the frequency of involvement of the prostatic urethra and says that in the majority of cases that he has examined he finds gonococci in the prostatic juice. He calls attention to the possibility of infection dwelling in

this part while the apparent conditions are those of recovery. His method of examination of the prostatic secretion is as follows: "After thoroughly washing the posterior and anterior urethra with a solution of protargol. I insert a sterile endoscopic tube to the end of the membranous portion and cleanse the mucosa in the field of absolute dryness. This cleansing is done with sterile cotton tampons. I then take from the tube the juice obtained by massage and examine it. In some cases I limit my work to thorough washing of both urethral divisions and avoid expelling the juice removed from the prostate by massage, by pressure upon the pendulous portion, as is often done. By this latter manipulation the contents of the glands and lacunæ of the anterior urethra are expressed and the results obtained are consequently not free from objectionable features. Even without pressure upon the pendulous portion, prostatic secretion almost invariably presents at the meatus several moments after prostatic massage. The examination by means of the tube must always be followed by washing of the anterior and posterior urethra. The fact that of 37 cases I examined in this manner one was affected with epididymitis fourteen days later, shows that no danger to the patient is incurred thereby." He explains the cystic changes that may occur from the continuance of the condition. It is only by the finger that the proper diagnosis can be made. Rigid instruments are inadequate and may have had results. If gonococci are present he finds the use of a silver preparation advisable; protargol is best. If other bacteria be found, a mild solution of corrosive sublimate is of use for irrigation. It is important when other bacteria than the gonococci are present to give attention to thorough asepsis of the lowest portion of the intestinal canal, and he considers local treatment by massage injurious when there is any elevation of temperature. As a prophylactic method against the occurrence of gonorrheal prostatitis he has adopted the following plan: "After the microscopic diagnosis is made, the patient is ordered to urinate. If the second urine be clear, the anterior urethra is gently irrigated with a 0.25 per cent. solution of protargol until the solution flows off clear. If the patient be hypersensitive, the urethra is cocaineized with a weak solution (1 to 200), to which some protargol is added as a precautionary measure. Then, closely following Janet's directions, a copious irrigation is applied to both urethra with the same protargol solution. The fluid is allowed to enter the bladder until the patient experiences a desire to urinate; this requires about .25 to .5 of a liter. The patient then empties his bladder. This procedure is repeated on the two following days. After the first twenty-four hours have elapsed, the discharge, which was purulent and abundant, has become sparse and serous and in most cases gonococci can not be found. Leucocytes disappear in a similar manner and the specimen shows only an abundance of epithelia and fibrin. If, however, gonococci persists to the third day, it shows that the disease has not been aborted. The cause of the failure is that the prostate was already infected, or that para-urethral passages exist, in which gonococci are beyond the reach of treatment, or deformities of the urethral mucosa, folds, or valves may be the cause of the failure. In the latter cases slight surgical intervention brings immediate relief." He has treated 60 cases in this manner with very good results, showing that in a large number of the cases rapid disappearance of the gonococci can be secured by this abortive method if undertaken sufficiently early.

**28. Prostatic Hypertrophy.**—The symptoms and diagnosis are first noted by Schöler. The prognosis depends on the early diagnosis and prompt treatment. He has no confidence that drugs will affect the growth. Massage, he thinks, is also useless and may be harmful. Catheterization, while palliative, is almost invariably liable to produce infection. Dilatation has its best results in incipient cases and better effects will be obtained if the patient is made to understand the necessity of frequent seances and their long continuance. Cystotomy is a temporary or procrastinating procedure and is most useful where the bladder is affected or cystitis exists as a complication and it also offers a chance for better examination. He thinks we need a better knowledge of the anatomy of the

gland. Its pathology calls for an advance in our therapeutic resources for something more than to temporarily relieve the constant threat to the life of the patient.

**29. Blood Serum Test.**—Wood briefly reviews the history of blood antisera as a test and describes the method of preparing rabbits to obtain the serum. He has recently applied the serum test in a murder case now on trial and obtained positive results.

**30. Blood Serum Test.**—Whitney has tried two parallel series of experiments with hydrocele serum and blood serum and finds a better reaction of one in one case and of the other in the other. He thinks that further experiments are necessary before it can be decided whether the hydrocele fluid or the ordinary blood serum is most effective. The only indication that we have beforehand whether a rabbit will yield a strong antiserum is the apparent slowness of the coagulability of the blood in those that have given the best reactions in his observation. If this is more than a coincidence it might be used in selecting the animal for injection. He insists on the importance of the blood serum test in medicolegal cases.

**31. X-Light.**—Rollins first describes certain apparatus and criticises the patent law under which previously published methods or appliances have been patented. He believes that we should use much more powerful apparatus and have it at greater distance in therapeutic work. All kinds of  $x$ -light may produce burns. The kind should depend on the seat of disease. For superficial disease we should use radiation from a tube of low resistance which is most easily absorbed by these tissues; if we wish to treat internal diseases, we should use the radiation from a tube of high resistance, which is less absorbed by the superficial tissues and is more available for affecting the internal organs. He says we need powerful apparatus and should encourage experimenters who are working to produce such. At the present time the most important problem is to find instruments for measuring the intensity of  $x$ -light. One of the required instruments should quickly show the therapeutic power of the  $x$ -light and another should tell its full photographic intensity, which, until we get an actinometer, should be judged by a tungstate of calcium screen and not by one of platinocyanid of barium. Until we get  $x$ -light powerful enough to take instantaneous photographs of the heart and other organs we should not slacken our endeavors to construct and use more powerful apparatus.

**42. Laryngeal Tuberculosis.**—Freudenthal reports the results of 29 cases on which he has operated: only about one-half the total number. Of these 29 thoroughly recorded, 7 showed slow amelioration and 4 almost immediate improvement. Of the 18 unimproved cases, 13 were in advanced stages of pulmonary phthisis, 5 were in the earlier stages. None of them received any benefit from curettement, and the majority, indeed, thought their health was hurt by the operation. In many of the cases he was of the same opinion himself. From his results he is led to believe that patients do just as well without curettement and are perhaps better off. He has applied this idea for one year without doing any curettement and remains of the same opinion. There are two conditions to be met when we operate—intense pain and dyspnea. He leaves the covered infiltrations alone as long as possible to avoid producing ulcers, but treats topically in most instances with his orthoform-menthol emulsion described in *THE JOURNAL* of March 16, 1901. This will usually relieve the patient if it can reach the spot. Where we can not apply it, however, he would recommend curettage in some cases when no other means will relieve the pain of the patient, though admitting that relief will be very temporary. In case of laryngeal dyspnea we must in some way relieve the condition. The question is, what are we to do? He never recommends tracheotomy except in very urgent cases. Laryngofissure would be more advisable, but most patients can not stand such an operation. The only thing left is curettage. In the last two years he has done very little in the way of operating in these cases, but considers there are a few cases in which endolaryngeal procedures are of some benefit.

**44. Intratracheal Medication.**—Barton holds that the ob-

jections to intratracheal medication of its interference with respiration and excitation of severe cough are fallacious. The sensitiveness is largely confined to the larynx and what goes below that produces little trouble and often immediate relief. His wider experience has led him to hold such objections groundless. The ordinary aspirating syringe holding 2 drams, with curved endolaryngeal tube seven inches in length, can be introduced by the physician, the patient sitting with his tongue drawn out and head thrown back. The tube should be introduced in the median line, carrying the curved portion over the base of the tongue, raising the elbows high enough to insure the point of the tube passing under the edge of the epiglottis. The patient is instructed to avoid swallowing, to keep the tongue well drawn out, and to take a deep inspiration. As he inspires, the contents of the syringe is thrown quickly into the larynx, the ingoing current of air causing it to pass directly into the trachea, producing almost no laryngeal irritation. The intratracheal medication probable has some of its good results by affecting the nerve system of the whole body, as it is probable that the action can not be confined entirely to the part. It excites the vasomotor and trophic systems and at the same time it acts as a local treatment to the dilated mucous surfaces. He does not offer it as anything like a real cure for tuberculosis but is a powerful adjunct to other treatment.

**45. Serum Treatment of Tuberculosis.**—Pottenger concludes that culture products do have a specific action upon tuberculous foci. The early unfortunate experience with tuberculin has obscured this fact by its use in too large and frequent doses and in unsuitable cases and it was held responsible for all postmortem findings. The field of usefulness for culture products is where recent tubercles are found, especially in incipient cases. If used in advanced cases they will help to remove areas of recent infection, but must not be expected to remove dead, decaying or newly-formed tissue. Where used they should be reinforced by every measure at command, proper hygienic and dietetic measures prescribed and the patient's health attended to. If properly managed and used the proportion of cures is greater than when they are not employed and they produce an immunity protecting the patient from relapse and make a permanent cure more often than hygienic and climatic treatment alone, which facts should be sufficient to warrant their employment.

**55. Hemorrhoids.**—Nassau describes the method he learned while assistant to Halsted in the Johns Hopkins Hospital. It consists essentially in slight stretching of the sphincter not paralyzing the muscle, putting a gauze tampon well up into the bowel with the speculum and then making a circular incision just within the margin of the skin. This incision includes more than one-half the anal circumference and is carried into the wall of the rectum until the fibers of the external sphincter are reached, which latter must not be injured and, as a rule, can be easily stripped from the rectal wall. The bowel can then be readily pulled down until the dissection is carried above the hemorrhoidal area. During the operation, bleeding vessels must be caught as soon as they are cut or previously where this is possible. Before the incisions are closed all bleeding points caught by the artery forceps should be tied. In this method of operating, secondary hemorrhage never occurs, providing the bleeding vessels are ligated. As a rule, it is not necessary to include the whole circumference of the bowel, if care has been taken to leave the healthiest portion unincised. At this stage the hemorrhoids are cured, that is, the blood supply is completely cut off. Three interrupted subcutaneous silk sutures are placed in position to anchor the bowel to the skin. Each stitch includes the walls of the bowel, but does not puncture the mucous membrane. The redundant hemorrhoidal tissue is then cut away by transverse incision, the bleeding points are ligated and the skin and mucous membrane are closely approximated by interrupted sutures of fine silk. If a complete circular incision is required, the anchoring sutures are introduced and the remaining work finished before the introduction of the final stitches. To obliterate any "dead space" a one-half inch rubber tube four inches long is wrapped in gauze until it has a diameter of one inch and then covered with boric acid ointment and placed in

the rectum so that it protrudes slightly. This should be done with the speculum. A cord should be passed through the protruding end of the rubber tube to facilitate removal. This rectal plug should be removed in six to twelve hours, though he has left it longer. An opium and belladonna suppository will relieve tenesmus. On the fourth day the bowels are moved by divided doses of calomel or by enemas of cottonseed oil followed by soap and water. The patient may get up on the sixth day and be discharged on the tenth. The operation can be performed under local or general anesthesia. Full asepsis of the parts, thorough washing and sponging, preliminary cleansing of the bowel are, of course, required. He asserts that the advantages of the operation are as follows: "1. The sphincter is not injuriously dilated; 2, the wound is not open to infection from the bowel; 3, the blood supply to the pile-bearing area is obliterated; 4, in the majority of cases little and in some no tissue is excised; 5, healing is rapid; 6, recurrence is a rarity."

**64. Deciduoma Malignum.**—Ladinski reports a case of this disorder and analyzes the symptoms. He considers it a special form of malignant disease associated with the reproductive function and different from the ordinary malignant uterine growths. The clinical features which should aid us in reaching a diagnosis are: "1. History of recent parturition or abortion, especially if a hydatid mole has been discharged or placenta retained; 2, profuse hemorrhage occurring at irregular intervals, without apparent cause, not amenable to the ordinary means of treatment and which recurs in spite of repeated curettings, there being a constant sanguineous discharge during the intervals between hemorrhage; 3, a persistently large and hyperplastic uterus and cervix, with a patulous os; 4, pain in the pelvis; 5, anemia, rapid loss of flesh and strength and cachexia; 6, characteristic nodule in interior of uterus in the early stage; 7, the presence of metastatic deposits, especially in the vagina and lungs, the latter producing cough and bloody expectoration." The prognosis is bad though there are records of 51 recoveries out of 124 cases. It should be remembered that recoveries are reported where only the immediate results of treatment are recorded and the mortality loss would probably be much increased if the data were complete. The causes of death in these cases were metastases in other organs in 47 cases, labor and exhaustion in 20, perforation of the uterus and uterine hemorrhage in 4 cases, operation, shock and sepsis in 2 cases. The lapse of time between the termination of pregnancy and death as it occurred after mole, labor at term or abortion were from three days to six years in mole, and two weeks to one and one-half years in abortion cases and from one to nine months after labor at term. The average was from four to six months. The only treatment is the operative; especially in any case of hydatid mole the pregnant uterus should be emptied as soon as possible after the character of the pregnancy is ascertained. If microscopic examination of the cyst shows any atypical proliferating cells or if there are any symptoms of malignant degeneration of the uterus, he thinks it is within the limits of conservatism to agree with Neumann that the uterus should be extirpated. Every patient whose history is the least suspicious should be submitted to a microscopic examination and thorough exploration at the earliest possible opportunity. The paper ends with summaries of 132 authentic cases and an extensive bibliography.

**65. The Menstruating Uterus.**—From a study of the subject and the literature, Findley concludes that menstruation is shown to be not a shedding process; the loss of epithelium is purely accidental and limited. Previous observations which indicate it otherwise were at fault in the selection of material which had undergone cadaveric and degenerative changes.

**66. Short Cord.**—Brickner calls attention to a symptom of short cord, consisting of frequent, jerky discharge of urine in the intervals of the pains of the second stage, which is easily interpretable, significant of the condition and of no other, and logically explainable. He summarizes the diagnostic points of short cord in the order of their importance as follows: "1. Recession of the head in the intervals of pains; 2, urination in small quantities in the intervals of pain after the establishment

of the second stage; 3, arterial bleeding during and between uterine contractions; 4, pain over the placental site, especially during a uterine contraction or during the application of the forceps; 5, a desire of the patient to sit up; 6, uterine inertia."

**67. Appendicitis.**—From a microscopic study of selected cases of appendicitis Manton concludes that: "1. Appendicitis is never an uncertainty, never a doubtful condition. 2. It is in all its forms a serious disorder, fraught with the gravest dangers to somatic health and life itself. 3. It is always a surgical disease and, as such, should not be subjected to the dangers and insufficiencies of medical treatment."

**73. Albuminuria in Pregnancy.**—The significance of albuminuria in the urine in pregnancy is considered less important by Morse than it is usually held. The weight of evidence, he thinks, seems to be against the reliability of albuminuria as a symptom of serious importance and careful urinary analyses show definite relation between urea and the development of toxic symptoms.

**78. Tuberculosis of the Testicle.**—This article is a review of the literature and of the various opinions of authors. Abell finds the following deductions warranted: The epididymis is the most frequent starting point of urogenital tuberculosis. It is usually secondary to some other focus, but may be a primary deposition. The testicle is rarely primarily affected, but as a rule secondarily so from the epididymis. When the epididymis is primarily infected through the blood supply, the process is probably an intratubular one; the same is the case when it is secondary to other urogenital foci in other parts of the genital tract, and even distant lesions do not necessarily contra-indicate operation, since, when operated early, there is evidence that the foci in the genital tract recover as a rule and frequently healing of a distant lesion has been observed following the operation. Castration should be limited to those cases in which the process has invaded the testicle proper. Epididymectomy with high resection of cord after the method of Vileneuve is to be practiced in all other cases.

**87. Pyloric Stenosis.**—The symptoms of this condition are described by Saunders and several cases reported. He notes the intermittent character of the symptoms in some cases and suggests a spasmodic action of the pylorus with secondary hypertrophy as held by Thomson and Pfandler. The treatment should be the use of some drug that will overcome the violent contraction of the pylorus, as such he recommends belladonna, bromids and chloral. Opiates should not be given, as they impair the function of the stomach. For the treatment of secondary gastric irritation, the stagnated contents should be washed out and rectal feeding resorted to from time to time; nothing but water being given by the stomach for twenty-four hours or more. When oral feeding is again resumed, the stomach should be washed out occasionally to remove a possible residuum of undigested food. The diet should consist of food which forms no coagulum in the stomach, and this has not been sufficiently emphasized. Milk or any food containing undigested casein will not answer, therefore breast feeding by the mother is usually unsuitable, while the milk of a wet nurse in advanced lactation may succeed. Whey or peptonized milk or a mixture of both is generally the best food. The deficiency in fat should be supplied by cod liver oil, and a very small percentage of cream may be gradually added. The end to be accomplished is hypertrophy of the gastric wall without dilatation, hence the quantity of food should not be large. Gaseous distension of the stomach should be prevented. When the infant is failing in spite of rational treatment, surgical intervention should be advised.

**88. The Leucocyte Count in Children's Disease.**—Head, from his study of the subject, concludes that the blood count in sick children from two years upward is as noticeable and fixed as in adults suffering with the same diseases, and the information furnished is as reliable. The procedure should be followed more generally by physicians.

**89. Enlarged Bronchial Lymph Nodes.**—Friedlander finds this to be a very frequent condition. In 123 autopsies made at the New York Foundlings' Hospital, tubercular lymph nodes

were found in every case irrespective of the cause of death. The mechanism of the introduction of bacilli to the parts is explained; it is frequently from adenoids. The outcome, however, is generally favorable if properly treated. The principal early symptom is a peculiar paroxysmal cough, with frequent attacks at night and dyspnea without cardiac lesions. The physical signs may be lacking at this stage. Broadly stated, the physical signs of enlarged bronchial lymph nodes are always those of compression; inspection and palpation may afford suggestive facts. Percussion and auscultation may often be of value as may be dulness over the sternum and exaggerated respiratory murmur in the interseapular region. Cough without known cause, anemia, indigestion, etc., especially after the acute exanthemata, must be suspected. The main articles of diet should be milk, eggs and meat, with plenty of butter. An excess of starchy foods should be avoided. The patient should be kept in the open air and taken from school. The bowels and kidneys should be kept active. Three drugs are of special value, iodid of iron, cod liver oil and creosote. Creosote itself has apparently a specially good effect on the enlarged nodes. We must be prepared to arrest definitely a localized tuberculosis before general infection has ensued.

92.—See abstract in *THE JOURNAL*, xxxvii, p. 853.

97. **Compression of Carotids.**—In 18 cases reported by Crile, one or more carotids were closed, both in 10; one common carotid in 5; and one external carotid in 3. In all there were 28 closures of individual vessels. The ages of the patients varied from 7 months to 69 years. There were no deaths attributable to the temporary closure of the arteries and no later cerebral effects. Less anesthetic is necessary with closed arteries, especially in the cases in which common carotids are closed; there may be an embarrassed respiration. There were no appreciable late effects upon the vessel walls at the point of clamping. The operating time was much diminished on account of the freedom from blood, and the amount of blood lost was very much less. The application of the clamp may be accomplished through a very small incision and in several minutes. The proper interpretation of a slowed or of an accelerated pulse or of reflex inhibition of the heart from mechanical stimulation of the vagus or its branches by the use of atropin and cocaine, the safe and absolute control of hemorrhage by temporarily closing the carotid arteries render operative procedure of the head and neck so much safer as to greatly increase the surgical possibilities. The compressing clamp blades were covered with rubber tubing, and the walls only approximated, not compressed.

99. **Prostatectomy.**—Syms describes his method and experiments and holds that prostatectomy is a primary and practical surgical procedure in suitable cases. It should be employed early. He believes prostatectomy by the perineal route to be the safest method thus far proposed for the radical cure of these great sufferers.

100. **Intestinal Obstruction from Meckel's Diverticulum.**—Halstead reports a case and describes the different methods in which the diverticulum may produce intestinal obstruction. He has collected 69 cases from the literature showing the treatment and operation in these cases. It is notable that among the last few cases reported, mostly by Chicago operators, the recovery rate was greatly in excess of the average in the literature of this condition.

101. **Meckel's Diverticulum at the Navel.**—This paper by Hubbard describes the origin of diverticulum patent at the navel, discusses the diagnosis, treatment and prognosis and reports a case of his own observation which was operated on with success. The existence of fistula discharging fecal material at the navel is essential for the diagnosis. The history is of importance to distinguish it from abscess and umbilical hernia caught in the ligature about the cord and left as a fistula by the falling of the cord. Umbilical hernia also protrudes on coughing or straining, which a diverticulum is said not to do and its outside is covered by serous, not mucous membrane. In the later stages the diagnosis may be more difficult. An open urachus must also be distinguished. The

direction taken by the probe and the character of the discharge are the main points of difference. Spontaneous cure is a rarity. Compression should be made as soon as the diagnosis is complete, but in complicated cases operation seems to afford the only chance of cure.

104.—This article appeared in *THE JOURNAL* of March 29, p. 803.

110. **Perforation of the Nasal Septum.**—This condition is not infrequent, it may occur at all periods of life and Richardson thinks it possible that it may be congenital. The most frequent type is that from syphilis. The characteristic local lesions of the disease, of course, must be noted. There are certain cases, however, where there is no pathologic evidence of organic disease. Among them are probably rare congenital cases. All cases where the perforation is slightly within the osseous septum involving the cartilage and bone, in which trauma, tuberculosis and lupus could be excluded, Richardson would without hesitation regard as syphilitic, even without history or evidence of constitutional taint. The possibility of producing perforation by boring with the finger-nail against the septum is hardly to be considered as tenable. All the theories advanced are enumerated by the author, and except Rosenfeld's, have in common a localized change taking place in the arterial supply to a limited area of the septum. It may be due to irritation, by drying of the mucosa, etc. He himself is inclined to believe in a destruction of the innervation of the cartilaginous septum whereby the resisting power of the structure is so impaired that an ulceration with molecular destruction of the cartilage takes place. Preponderance of perforation of the cartilaginous septum in persons affected with tuberculosis or with strong tubercular histories is rather more than a simple coincidence and he thinks that these infections are liable to produce a lack of resistance which may lead to degenerative changes with or without the characteristic histologic elements of tuberculosis.

114. **Syphilitic Lesions of the Nose.**—The salient points here noted by Cobb are summed up as follows: "1. Internal medication should be pushed to the limit of toleration for the individual case. 2. Prolonged hot baths are of use in bringing the patient quickly under the influence of antisyphilitic medication. 3. In syphilitic lesions of the nose and throat, we have infection by other bacteria and must therefore use antiseptics freely. 4. The local use of mercurials renders these lesions as amenable to treatment as external syphilitic ulcerations in other parts of the body."

115. **Laryngeal Tuberculosis.**—Brown has used intratracheal injections for chronic laryngitis and laryngeal pulmonary tuberculosis in a number of cases with advantage, using the same material as is used for stimulating sprays, viz., 1 to 2 per cent. menthol, .5 to 1 per cent. thymol, and 1 per cent. guaiacol and creosote solutions. Every patient that has been treated thus far has experienced benefit.

116. **Treatment of the Eustachian Tube by the Electro-Bougie.**—Harris draws the following conclusions from his experience as regards the use of the electro-bougie in morbid conditions of the Eustachian tube: "1. The electro-bougie has a place in our aural therapy—though a less important one than was at first supposed. 2. It should be used after and not before other methods of treatment. 3. It will be most liable to fail if any associated internal ear disease is present. 4. Its results are not always permanent—the stricture may reform—we may hope rather for a diminution than a disappearance of the tinnitus. Two cases were totally and 2 partially relieved out of 25. 5. Its use is not without danger—a proper knowledge of the anatomy of the parts and of the technic is essential. 6. It is a question whether the process is a true electrolytic one, or if in many instances the obstruction is a true fibrous stricture."

123. **Fistula in Ano.**—The following are the points made by Gant in regard to the relations of fistula in ano to tuberculosis: "1. Tubercular fistula of the anus is usually secondary to phthisis. 2. Pulmonary tuberculosis is rarely, if ever, secondary to anal fistula before or after operation. 3. Tuberculosis of the anal region should be dealt with as radi-

cally as when it attacks other organs. 4. When the patient's condition permits we should operate on fistulæ irrespective of kind. 5. We should not decline operations in persons suffering from chronic phthisis, nor in those who give a family history of tuberculosis. 6. Patients operated on for tubercular fistulæ complicated by phthisis and patients who are non-tuberculous but suffer from some involvement of the lung, and who rapidly decline and die after the operation, do so from an inflammation of the lungs induced by the anesthetic, especially ether. Such accidents have not followed operations in my practice where local anesthesia was employed. 7. Lastly, I believe we are justified in discarding the teachings of writers who teach that the cure of fistulæ will result in the development of phthisis."

124. **Typhoid Fever.**—Robin describes his method of preparing active cultures of typhoid germs for the Widal test and for Ehrlich's diazo-reaction. We have not space to reproduce the details here.

136. **Molluscum Contagiosum.**—From a careful study of the growths in this condition, which includes examination of several hundred sections in tumors, and of the literature, White and Robey conclude that no one has ever demonstrated any parasitic body in the growth and that the change is not a colloid or hyalin degeneration, but rather an extraordinary metamorphosis of rete cells into keratin.

137. **Malignant Tumors.**—From the results of culture experiments which are tabulated Richardson confirms the finding of his previous experiments that it was impossible to cultivate from the tissues and fluids of malignant new-growths anything which can be regarded as a specific infecting organism.

139. **Relation of Blastomycetes to Cancer.**—From experiments reported and a study of the results obtained by others, Nichols finds that certain blastomycetes can live and multiply in human and animal tissues, produce local lesions and metastases in the internal organs, that is, they are pathogenic. The lesions produced in animals by spontaneous infection are acute inflammations and abscesses or nodules of peculiar granulation tissue. This proliferation of epidermis is not analogous to the proliferation of epithelium seen in cancers, since no epithelial metastases occur. Blastomycosis in human tissues is rare. The lesions produced in animals are, with the exception of Sanfelice's "successful" cases, inflammations or nodules of peculiar granulation tissue. He describes Sanfelice's results as being in direct opposition to other writers and logically explained by coincidences and not as results. Blastomycetes, as a rule, cause marked proliferation of tissue and little infiltration with leucocytes; their toxic powers are small. They primarily extend along lymphatic clefts and vessels, rarely in human beings, and more often in spontaneously infected animals blastomycetes may be taken into the blood vessels, carried through the body, and produce a general infection and metastases. The secondary nodules have the same general character as the ordinary ones. The morphology of so-called "cancer bodies" is not identical with that of the blastomycetes, and they are not constantly present in human malignant tumors and cancers. Even if they do occur in human cancers they are not in such numbers and in such a relation to the anatomic lesion as to justify the belief that they are the cause of the disease. All the facts lead to the ultimate conclusion that there is no evidence that blastomycetes have anything to do with the production of human cancers.

141. **Cancer.**—Nichols offers the following summary as the result of the lines of work pursued during the past year under the direction of the Cancer Commission: "1. The lesion produced by the coccidium oviforme is essentially a process of chronic inflammation and is not analogous to the lesion seen in cancer. 2. The lesion in molluscum contagiosum is characterized by certain changes in the epidermis, is not due to the action of a protozoön and is not analogous to cancer. 3. The so-called "blastomycetes" (saccharomycetes) of Sanfelice and Plummer are torulæ. 4. The lesions produced by these blastomycetes are essentially nodules of peculiar granulation tissue and not cancerous, not in any sense true tumors. 5. Blastomycetes are not constantly present in human cancers

6. The peculiar bodies seen in the protoplasm of cancer cells are not parasites, nor the cause of the lesions, but probably are, in part at least, atypical stages of the process of secretion by glandular epithelium."

2. Antral Disease.—After first describing the anatomy and variations of the maxillary antrum, Tilley passes to its affec-tions. His experience leads him to believe that dental caries is by far the most frequent cause of chronic antral empyema. Although the crown of the tooth may seem healthy, there may be disease at its roots, carrying infection to the antrum. Abscess may be present between the roots of a tooth which possesses a healthy crown. The supposition that the dental trouble is secondary is hardly reconcilable with the histories of the cases. In some of his cases on which this paper was based, the ethmoidal, sphenoidal and frontal sinuses were also in-volved. The symptoms are diverse and the frequency of their variation is one of the striking features of chronic antral sup-puration. A straightforward case manifests itself by purulent nasal discharge, the patient only being conscious of an offensive smell. There may be also a congested or polypoid state brought on in the nasal mucosa and various degrees of nasal obstruction. During sleep the discharge tends to pass back into the pharynx, producing, on awakening, hawking and sniffling in the morning. Still more serious symptoms that call the patient to seek relief are headache and neuralgia—which may be intense; and the gastric symptoms due to gastritis from swallowing septic matter. Pharyngeal and laryngeal irritation may occasionally be present, and in less frequent cases aural symptoms also occur. In one of his patients the symptom that led him to seek relief was the occasional discharge of blood into the mouth from the back of the nose. Taken altogether, he believes that antral suppuration is more common than is generally assumed and that many cases are overlooked. In making the prognosis, we must consider the original infections. The purely dental cases are the most hopeful. The period of time which has elapsed and the consequent degenerative changes, the general health of the patient, the persistence and regularity with which he will follow the prescribed treatment are also to be considered in the prognosis. If, with the symptoms mentioned, purulent dis-charge is seen in the middle meatus which accumulates after removal when the head has been held for a few minutes so as to drain the ostium and on transillumination the suspected antrum is less translucent than its fellow, the diagnosis is aided. Finally, intranasal exploration and irrigation of the antrum will give conclusive proof. In using transillumina-tion we should remember that it is the infra-orbital trans-lucencies rather than those of the cheek which must be com-pared. The opacity is due to a thickened mucous membrane of the antrum and not to an accumulated discharge and there is the possibility of mistakes from a tooth plate left in the

mouth. Intense opacity in an adult extending from the orbit to the lower part of the cheek, and associated with pain and distension of the cheek, should suggest malignant disease. The treatment comprises two methods: the first is by drainage and irrigation through the opening in the alveolus, kept patent by a silver tube. The opening is generally made through the socket occupied by the first molar or the second bicuspid. The tubes should be removed twice daily, and some simple antiseptic lotion like boracic solution or Condy's fluid injected by a suitable syringe. The best form of the latter is a modification of Higginson's enema syringe. These injections may be less frequent as the discharge diminishes; even after the interval of a week, if no discharge returns with the lotion, the tube may be removed and the case considered cured. Occasionally the hemorrhage following alveolar puncture may be a little troublesome; neuralgia has been caused by too large a tube. In 34 of the 35 patients this was the method of treatment. In but one case was the second method employed, namely, the radical operation or exposure of the anterior surface of the antrum through an incision made along the gingivo-labial fold extending from the level of the first molar to the canine tooth, and removal of a portion of the antral wall the size of a sixpence followed by curetting of the diseased mucous membrane lining the sinus. A counter-opening is made into the inferior meatus of the nose, which should be as large as the other. After thorough disinfection of the parts the sinus is plugged with a strip of antiseptic gauze, the proximal end of which is passed through the naso-antral opening and cut off level with the nostril. The bucco-antral wound is united by fine sutures, or allowed to close by granulation as rapidly as possible. The packing is removed from the nose in forty-eight hours and irrigation is kept up through the naso-antral opening for some three or four weeks, by which time the discharge should have ceased. He believes the alveolar method should be advised in the first instance because of its simplicity, drainage from the most dependent part, and the ease and shortness of the operation. The only exception he would make would be with a patient whose circumstances demand as short a treatment as possible and in whom one found the nasal mucosa in the middle meatal region in such a state of advanced polypoid degeneration as rendered it practically certain that a similar condition was present in the antrum where the only chance for success would be careful curettage followed by free drainage. He mentions the infrequency of this operation because it has been recommended as a general operation by other authors.

**3. Asch's Operation.**—Yonge reports his experience with this method and finds that it is one of considerable value, which runs the risk, however, of being very imperfectly carried out. The operation should be very carefully performed and the surgeon satisfied that recalcitrant segments are thoroughly broken at their bases. The patient must not be allowed to look after himself, but be carefully watched for at least ten days and the surgeon should make sure that the septum is solid in its new position.

**4. Palatal Deformities.**—Whitehead's article reviews the theories of the agency of nasal and pharyngeal disease in the production of palatal deformities and holds that no single one is sufficient to fully explain their mode of production. It is certain, however, that interference with nasal respiration is capable of producing serious and extensive degeneration of the teeth and jaws, and that, by the restoration of nasal breathing, this disfigurement of the maxilla can be prevented, and, if seen at an early stage, alleviated, the constant stream of air developing and expanding the upper jaw.

**6. Chloroform.**—This final article by Embley reviews the cause of the fall of blood pressure in chloroform administration. He finds that the drug causes a diminution in the vascular tone of arterioles. This is most obvious when it is practically kept out of the brain. The central vasomotor system is stimulated, at any rate for a time, by chloroform and the cause of the fall of blood pressure from the administration of chloroform is paralysis of the muscle cells of the heart and of the arterioles (provisional). The fall may be further augmented by slowing of the heart's rate, or suddenly brought to zero by vagus in-

hibition. The relation of asphyxia to syncope and the causes of respiratory failure are also investigated and the following conclusions deduced: Failure of respiration is mainly due to fall in blood pressure. With a good blood pressure, failure of respiration by inhalation of chloroform is practically impossible. Restoration of failed respiration is dependent upon restoration of blood pressure. Failure of respiration occurring in the induction or early period of anesthesia happens as frequently after as it does before the heart stops. The effects of chloroform vapor breath upon the respiration are summarized as follows: "1. The blood of the lungs, by once traversing the pulmonary capillaries, does not attain to nearly the same vapor tension of chloroform as that of the air inspired. 2. The vapor tension of chloroform in the arteries is the important practical question. As this rises and falls with the volume of chloroformed air inspired, also with variation in vapor tension of the chloroform in the air, it follows that the effects of chloroform upon the animal will vary with the depth and rate of the respirations, just as much as with the percentage strength of chloroform vapor in the air administered. 3. Chloroform in arterial blood is largely discharged into the tissues at first—that is, the vapor tension of chloroform in the venous blood is equal to that of the tissues. As the arteries continue to pour more chloroform in, the vapor tension of chloroform in the tissues and venous blood would gradually approximate that of the arteries. 4. The range of percentage of chloroform vapor in the air inspired, for inducing chloroform anesthesia in the same period of time in different dogs, varies between 0.8 per cent. and 2.5 per cent. 5. Two per cent. or upwards of chloroform vapor in the air inhaled is liable to bring on dangerous vagus inhibition." The general conclusions, which are briefly discussed, are that the heart muscle is very sensitive to the poisonous effects of chloroform. Chloroform raises the excitability of the vagus mechanism, particularly in the early part of the administration. The central medullary vasomotor system is stimulated, at any rate for a time, by chloroform and the failure of respiration in inhalation experiments is mainly due to fall in blood pressure. With a good blood pressure such fall is impossible and restoration of respiration is dependent upon restoration of blood pressure. The practical application of these results is not here considered, but one obvious moral is, use only weak vapor of chloroform (less than 1 per cent.) in the early stages, until the initial increased excitability of the vagus mechanism has given place to diminished excitability; in other words, take time in putting the patient under the influence of chloroform.

**8. Thoracic Phthisis.**—Roberts' third lecture reviews the various modes of onset, symptomatology, method of examination, both physical and general, including sputum examinations, tuberculin tests, agglutination tests, Roentgen rays, etc. The details are too numerous to be here given. He submits the following general propositions in regard to thoracic phthisis: "1. The natural tendency of phthisical mischief involving the lung, especially if definitely tubercular, is to be progressive, and even an early and limited lesion gives cause for anxiety with regard to the future. 2. There is no foundation whatever for the supposed 'three stages' of the complaint from a clinical point of view, corresponding to the pathologic states of consolidation, softening and cavity. This is a popular error which the profession should do its utmost to suppress. 3. In not a few cases the progress of thoracic phthisis is very insidious, without any prominent local symptoms; this may happen even in acute and rapid cases, as well as in those of a chronic type. 4. It is very remarkable how, in certain acute cases of pulmonary phthisis, if not too advanced, arrest of the disease takes place, sometimes ending in a practical cure, especially if the patient can be placed under favorable conditions. In other instances, after rapid progress, it settled down into a chronic and limited form of phthisis. Acute pleuritic cases of definitely tuberculous nature are, as a rule, very unsatisfactory in their progress, but some striking exceptions are met with. 5. While recognizing the tendency of phthisical lesions to advance progressively, we must always be fully alive to the wonderful efforts of nature to

oppose and withstand them, to check their progress and to repair the damage which they have caused, even when the morbid changes are definite, extensive and of a destructive nature. The more chronic the case, the more likely are these results to happen. At the same time unaffected portions of pulmonary tissue may become developed and utilized for respiratory purposes, a development which it should be our business to encourage and to help. 6. It is extraordinary sometimes to note the combinations of chronic conditions affecting the chest with which patients may not only live but even get on fairly comfortably, especially when their circumstances and surroundings are satisfactory and they are prepared to exercise moderate care. As to cavities which are generally regarded with such terror, there are thousands upon thousands of persons who go about with these lesions, many of whom do excellent work, public as well as private, and all must be familiar with such cases. 7. Phthisical cases are always liable to variations in their progress, improvement or even apparent arrest of the disease taking place, followed by exacerbation and further activity. A considerable number of cases of winter cough are really of a phthisical nature. However quiescent a case may be, or even after a practical cure, the mischief is liable to start afresh, though it may be after a long interval; this is not an uncommon experience after a supposed cure by the open-air treatment. Accidental complications, sudden or acute, not uncommonly interrupt the course of events, being either serious for the time, but ultimately recovered from, or leading to an unexpected fatal termination very speedily or within a short period. 8. We must always be prepared for striking changes in the clinical aspect and phenomena of cases of thoracic phthisis during their progress, not only local, but also in relation to the various remote complications which may supervene. Hence a case often entirely alters in its features before the end comes. The final scene varies considerably in its characters, and may be very distressing; but in many instances the end is calm and peaceful, while the patient is, as is well known, generally buoyed up with hope even to the last. Sudden syncope is sometimes the immediate cause of death. Acute mania may supervene toward the close of life in chronic phthisis. 9. Another important point to be borne in mind is that sometimes a phthisical patient lingers on indefinitely when apparently almost moribund, especially when kept alive by devoted nursing and care. And further, an individual in advanced consumption who appears to be rapidly approaching the end occasionally rallies and picks up in a wonderful way, living for a long time afterwards, and, it may be, improving considerably. I remember several cases of this kind brought to the Brompton Hospital, their friends thinking that they had relieved themselves of all further responsibility, but the patients were afterward returned to their hands vastly improved, sometimes much to their disappointment." He suggests that we should be very cautious in the prognosis of these cases, especially as regards the future of the disease, as affecting the communities as well as individual cases. The "optimistic platitudes" now widely and dogmatically expressed are, in his opinion, doing serious mischief in various ways. Nevertheless, we should recognize the practical findings which have been made in the treatment, and the real diminution in the prevalence and mortality of the disease. He would warn the practitioner against anything like a definite opinion as to the duration of the disease.

9. **Organotherapy.**—Davies has reviewed the whole subject of organotherapy, giving the different extracts, etc., and the findings as to their therapeutic value.

12. **Cardiac Inadequacy.**—Morison reports cases of cardiac inadequacy of a heart small though hypertrophied, in which the defect under special conditions was, in part at least, the cause of the general decay and death of the organism. He thinks that, bearing in mind the underlying inadequacy or adequacy of cardiac action, we shall find the key to some of those circumstances of success or failure in the management of diseases and disorders of the heart which so frequently afford food for thought, and explain to some extent the secondary phenomena of cardiac failure.

15. **Diphtheria Antitoxin.**—The results of the antitoxin treatment in the Glasgow City Hospital are given here in tabulated form and discussed. The mortality at all ages has been greatly lowered, but Brownlee notices especially that the improvement has become more marked as the age period increases from 1 to 10 years. He also gives comparative tables of mortality in other localities in the pre- and post-antitoxin periods showing a similar reduction.

17. **Obstruction of the Coronary Arteries.**—The résumé of Cowan's article is given as follows: "1. The coronary arteries may be obstructed (a) at their origin; (b) in their course. 2. If the obstruction involves a main artery and the closure is gradual, compensatory enlargement of the other artery may prevent damage to the cardiac muscle, but perfect compensation is rare, and necrosis or fibroid change commonly ensues; if, however, the closure is rapid, sudden death is the usual result. 3. If the obstruction involves a small artery, no compensatory arrangement is possible, and the nutrition of the cardiac muscle will suffer, whether the closure is rapid or gradual. 4. (a) If the obstruction is partial, some of the muscle may degenerate (granular or fatty degeneration) and may ultimately disappear and be replaced by fibrous tissue. (b) If the obstruction is complete, some of the muscle will become necrosed (infarct) and the patient may die from slow cardiac failure or from rupture of the heart; if, however, the infarct is of small size, healing may take place, and a fibroid scar be ultimately formed."

27. **Malignant Pleuritis.**—Titoff describes four cases of cancerous pleuritis. The special points in diagnosing were the age—all of his patients were over 40 years old—the persisting pains on the same side as the lesion, the rapid reaccumulation of the exudate after puncture, the gradual transformation of the exudate from a serous to a sero-sanguine and hemorrhagic fluid, and most significant of all, metastases in the supra-clavicular glands. This latter sign may not appear until very late. Other points are the discovery of bunches of cancer cells in the exudate. They were frequently found in his cases. The persistence of the pain is almost pathognomonic. In tubercular or rheumatic pleuritis the pains and dyspnea may be severe, but they always subside after puncture. In these cases the amount of the effusion remained about the same even after puncture. In none of his cases was the cancer complicated by pulmonary tuberculosis. In one patient the malignant character of the pleuritis was diagnosed at the second puncture, the fifth day after the patient had been received. It was founded on the rapid reassembling of the fluid after puncture, the slight fever and the absence of articular lesions and of tubercular bacilli in the sputa. The patient was well nourished and her appetite had been good, with no dyspeptic troubles. This case illustrates the difficulty of tracing a metastatic cancer to its primary focus. The autopsy disclosed an unsuspected scirrhus of the stomach involving one-third of the organ. About the only measures that afford relief are morphin or compresses of a 10 per cent. alcoholic solution of menthol. Puncture gives no material or permanent benefit.

33. **Diseases and Accidents which May Simulate Poisoning.**—Brouardel's extensive experience contains many remarkable instances of sudden death from auto-intoxication or from rupture of a viscus which deceptively simulated the symptoms of acute poisoning. He has known albuminuria and diabetes to run a chronic course unsuspected by the subject. A crisis resulting in death in a few hours may be the first revelation of the evil. Sometimes the toxic accidents of an incipient infectious disease are so violent that they mask the more familiar symptoms and suggest poisoning. Disturbance in the circulation in the intestines from an internal strangulation, hernia or impacted gallstone or fecal scybala may induce sudden fatal symptoms. Socquet found 800 gm. of impacted feces in one such case and 8 kgm. in another. Brouardel has himself observed 5 cases of unsuspected cylindric stricture and retention of feces which caused sudden death, 1 of tubercular peritonitis and 1 of a sarcoma of the mesenteric glands. The examining physician should look for and exclude an over-production of

alkaloids or interference with their elimination before assuming exogenous poisoning. He cautions always to think of the kidney in cases of sudden death. The inability to eliminate the toxins elaborated after an unusually hearty meal or alcoholic excess is the cause of many deaths under the circumstances which suggest poisoning. In a fourth or third of all cases of sudden death no lesion can be discovered to which it can be referred.

**50. Hospitals and Universities in the United States.**—Kahn has been visiting the hospitals and universities of this country on a "mission gratuite" from the French Department of Public Instruction. He has only words of the highest praise for the hospitals which receive pay patients and have a certain number of free beds. But he calls our public hospitals "rudimentary." He mentions Bellevue, New York, as a type, and observes that such institutions have less financial support than the others and are frequently dirty. He deplores the fact that France has nothing to compare with the admirable system of trained nurses here.

**51. Goat's Milk.**—Barbellion has for years been an ardent advocate of the introduction of goat's milk for infant and invalid diet. He describes tests which show that the coagulum is soft and very soluble, like that of human and asses' milk, while the coagulum from cow's milk is much more compact and difficult to digest. Comparative tests with gasterin showed that while cow's milk was scarcely affected by it during twenty hours, human, goat and asses' milk was completely digested. He reports a number of cases showing the remarkable manner in which infants thrive on goat's milk. The Académie voted in favor of his conclusions as to the advisability of establishing numerous goat milk depots throughout the city. One of the principal advantages of the goat for this purpose is that it is refractory to tuberculosis.

**52. Resolutions on Preventive Serotherapy of Diphtheria.**—The conclusions deduced from communications by Netter and others, reviewed in *THE JOURNAL* of April 19, p. 1045, were voted as resolutions by the Académie. Preventive injections were recommended as harmless and effective, and indicated in families and especially in boarding schools, hospitals, etc., when a case of diphtheria has developed. Even in the absence of a case of diphtheria, the preventive injections may be indicated in measles and scarlet fever wards. The preventive action is less positive in cases of measles. The dose must be larger and must be repeated more frequently. Preventive injections do not by any means enable one to dispense with disinfection and isolation. They merely render these measures easier and more effectual.

**54. New Process of Dental Analgesia by Electricity.**—Regnier, chief of the laboratory of electrotherapy at the Charité, Paris, and Didsbury, dentist to the hospitals, announce that the means of obtaining the analgesia of a living tooth has been discovered. It is the application of the high frequency current to the gum and tooth for three to five or possibly eight minutes. They use a current of 150 to 300 milliamperes with electrodes of "stent" lined with tin foil. The gum must first be washed with permanganate and alcohol and the chair be entirely free from any metal parts. Teeth can be extracted or scraped without pain during the analgesia thus induced.

**55. Alimentary Gelatin Treatment of Glycosuria, Albuminuria and Hemorrhages.**—Laffont and Lombard have already proclaimed their opinion that albuminuria, glycosuria and capillary hemorrhages all owe their origin to a single factor, some modification of the blood, which can be revealed by cryoscopy. Normal blood does not injure the liver, kidneys, etc., but if the composition of the blood becomes altered, the scene changes, and their experience has shown that if the blood can be restored to its normal composition, the glycosuria, albuminuria or capillary hemorrhages observed soon vanish. Whenever some nutritional disorder modifies the composition of the blood and its cryoscopic properties, the physician and the patient are warned of the change by albuminuria, glycosuria or a hemorrhage. Whether this syndrome is accompanied by

an anatomic lesion or not, the condition is reparable if the cause which has produced and is maintaining it can be suppressed. Gelatin is able to accomplish this if taken in the amount of 15 gm. a day. It is a harmless means of treatment and there are no contra-indications. None of their numerous patients objected to the gelatin or found their digestion disturbed. It can be added to soups and other dishes or eaten as a jelly. In mild cases of diabetes the cure is the rule in ten to fifteen days. In all cases, the proportion of sugar to the liter decreases by about 10 gm. The length of treatment required in albuminuria is more variable. It should be kept up long after the subsidence of the symptoms. In case of hemorrhage from the uterus, the gelatin should be continued longer than for any other symptom, reducing it gradually to the ten days preceding the menses.

**56. The Question of Parasyphilis.**—This term—coined to denote affections of syphilitic origin but not of syphilitic nature—is denounced by Leredde, who thinks that it obscures the proper conception and treatment. Tabes and general paralysis can be referred to syphilitic antecedents in fully 90 per cent. of all cases, but the touchstone is the fact of their curability by intensive specific treatment. The half-hearted treatment instituted by most practitioners is of course ineffective, but the cure is almost certain when treated in the early stages by an injection of calomel every six weeks, with occasional intermissions of one or two months, and this treatment continued for three years. The longer the delay before instituting these vigorous measures, the greater the liability to secondary lesions and degenerations.

**57. Organic Medicated Milks.**—Flamini reviews the various attempts to produce a medicated milk by administering a drug to a cow or other milk-giving animal. The chief objections have been the uncertainty of the dose and the impairment of the health of the animal. Potassium or sodium iodid have always been the drugs experimented with, administered by the mouth. Flamini has been very successful in his experience with subcutaneous or endomuscular injections of a 5 per cent. oily solution of metallic iodine. The oily solution holds more of the iodine than an aqueous, while it is less irritating, and the elimination of the iodine in the urine proceeds much more gradually. He demonstrated that the drug was eliminated in the milk and in the urine, with twice as large a proportion in the urine. After the rabbit or goat was once saturated with the iodine, the elimination could be kept practically constant by injection of small doses at regular intervals of a few days. With these small doses the maximum of iodine in the milk was .12 gm. to the liter. A large proportion of the iodine in the milk is in combination with albuminoids, but more than half is in an organic combination. The composition of the milk does not seem to be altered by this addition of the iodine and the health of the animal does not suffer. His tests were made with rabbits and goats.

**60. Harmlessness of Epidural Injections in Children.**—Cathelin's technic for epidural injections of cocaine, etc., has been already described in *THE JOURNAL*, xxxvii, p. 150, 793, etc. They have been found extremely useful in the treatment of sciatica, lumbago, neuralgia of trunk and viscera, tabic crises, incontinence of urine, lead colic, etc. He has applied them on eleven children between 7 and 15 years of age. He injected 5 to 15 c.c. of physiologic serum or a .5 per cent. solution of cocaine. One child received as much as 19 cg. of cocaine without the shadow of any inconveniences. He asserts that children bear these epidural injections perfectly and they can be used without fear or danger. Owing to the extensive network of intraspinal veins absorption is remarkably rapid, but these epidural injections are chiefly valuable as an anodyne and as a practical method. The child is placed in the Sims' position and the postero-inferior orifice of the sacral canal is easily found. It is comparatively larger in children than in adults.

**62. Posterior Gastro-Enterostomy.**—Terrier's mortality in 22 cases, in which he performed Hacker's transmeso-colic gastro-enterostomy, has been 4.54 per cent. Hacker has reported a mortality of 36.8 per cent., Mehler 65.2 and Haberkant 42.8

per cent. in 49 operations. Terrier ascribes his success in large measure to his practice of lavage of the stomach at the first indications of regurgitation, vomiting and fever. He describes his cases in detail and calls attention to the extremely grave condition of 7 patients who yet made an uneventful recovery. He thinks that we should discriminate between those lesions which oppose a mechanical obstacle to the gastric functions and those which determine a kind of general infection. Every stricture of the pylorus, organic or not, may rapidly entail an extremely serious condition. Alimentation becomes difficult or impossible and intervention is indicated regardless of the patient's serious condition. But in case of lesions which act by intoxication and generalization, whose development is almost fatally slow, a serious general condition may contra-indicate intervention. Even under these circumstances, however, the intervention may achieve an unexpected success as in 3 cases he describes. The various stages of the operation as he has slightly modified it are illustrated and described at length. He always orders lavage of the stomach and artificial serum beforehand but no purge, a rectal injection at the most. The operating room should be exceptionally warm and the abdomen covered with a warm cloth. He prefers chloroform and takes every precaution to keep the patient warm with hot cloths and bottles of hot water as soon as the operation is concluded, even before he awakes. No food is given for twenty-four hours. The mouth should be frequently rinsed with a solution of boric acid or natural Vichy water. Antisepsis of the mouth and frequent gargles are an important protection against infection of the parotid glands and septic broncho-pneumonia. He does not hesitate to apply lavage of the stomach whenever the tongue is dry and the patient has acid or bitter regurgitations and temperature. He repeats the lavage several times if necessary and always accustoms the patient to it beforehand. The post-operative diarrhea is combated by lavage of the stomach and large intestine, bismuth and laudanum. There have never been any evidences of the *circulus vitiosus* in his cases.

**63. Thoracoplasty for Chronic Purulent Pleurisy.**—The principles that have guided Mignon in this intervention were to drain the cavity and to fasten the outer to the inner wall of the pleural abscess. The drainage must be permanent, wide and thorough. It should extend across the entire width of the lowest portion of the cavity. The exact size and shape of the pleural abscess can be determined only by digital exploration. The shape of the thorax has to be altered to correspond. The ribs must be resected to the height required by the size of the pocket, and each rib resected for a distance a little longer than the transverse diameter of the corresponding portion of the abscess. In one case described, four operations were necessary before complete recovery. The abscesses shaped like a pyramid are liable to be most difficult to treat. He never cures but brushes the walls of the thorax with dry gauze, rinses with hydrogen dioxid, drains with tubes and protects the surrounding skin with zinc oxid salve.

**65. Congenital Luxation of the Patella.**—Zesas has collected 64 cases of congenital luxation of the patella. Other members of the family were affected in the same way in 6. The age varied from a newborn infant to a man of 71. The luxation was bilateral in 31. It was complete and intermittent in 13; complete and permanent in 29. The tabulated cases show that all of the various methods of treatment devised to meet different conditions have been successful. The surgeon has only to choose for the individual case.

**68. Aspiration of Exudates by Fallopian Tubes.**—Below is convinced that the tube alters its position at times in order to aspirate exudates in the vicinity. He describes a recent instance in which he purposely elicited this function on the part of the tube. The patient was a woman of middle age, healthy except for rare attacks of renal colic. The pains at one time became unbearable and followed the right ureter, while a long tumor developed in the region of the ovary with indications of painful perimetritis. The vagina and uterus felt hot and dry. The latter behaved as if it contained placental

debris, the os tightly closed. The urine was full of pus cells, the temperature febrile and the chills and pain had reduced the patient so that an operation was impracticable. He deliberately called upon the aspirating function of the tube under these conditions by inserting a glycerin tampon in the cervix after administering a senna purge. In a few hours the cervix was dilated and a large quantity of aqueous or purulent fluid was evacuated through the uterus, with the disappearance of the tumors and complete restoration of the patient, who was soon able to resume her usual occupation as the renal pains subsided under lithion.

**74. Caput Obstipum.**—The arguments and numerous cuts in this article seem to sustain Voleker's theory that wry-neck is due to a sideward deflection of the fetal head in the uterus. The ear on the lower side of the head is pressed against the shoulder, while the other ear is compressed by the uterine walls. Study of such cases shows that all the lines that unite corresponding points of the two sides of the head converge toward the side of the deformity. All the unpaired points of the head lie in a curved plane whose center of curvature is also on this side. The conditions can be restored approximately to normal if this conception is accepted and appropriate treatment instituted at once, massage and passive reduction, re-enforced by a simple starch cravat.

**77. Incarcerated Hernia.**—Rothe states that Mikulicz allows taxis only within the first twenty-four hours in case of crural and small inguinal hernia. In case of a large inguinal hernia with comparatively wide opening, cautious taxis may be attempted as late as the second or even the third day. He believes that a timely operation is incomparably less hazardous than taxis done too late. This article reviews 12 cases in which taxis alone was successful, and 97 requiring herniotomy, with 35 additional in which there was gangrene. In one of the latter cases the patient has been in perfect health since the intervention three years ago. The hernia was the size of a child's head and the small intestine was gangrenous at several points. It was resected for a length of 2.15 meters. The details of all the cases are given.

**78. Solidity of Cicatrix After Laparotomies.**—Pichler has lately re-examined the patients treated with and without Mikulicz's improved drainage. He finds that this drainage—even long continued—does not affect the ultimate cicatrix that forms. The results depend on the presence and the extent of the inflammation. When the drainage was applied merely as a preventive measure, only 30 per cent. of the patients displayed a tendency to hernia later, while only 30 per cent. are exempt out of those tamponed on account of an existing abscess or cystic cavity. The later rupture usually occurred within a year of the operation. The improved drain which Pichler urgently recommends is a square of gauze with a long, strong silk thread passed through the center. The gauze is folded from the center like an umbrella and the point is placed with forceps at the deepest point to be drained. A second and still another of these long pouches are inserted beside the first or nearer the surface. The loose ends of the gauze project from the wound, which is closed above and below. When the tampon is to be removed the folds of the gauze are lifted and loosened in turn while traction is exerted on the deepest portion by pulling on the thread in the center. This loosening is repeated several times before the gauze is actually removed, copiously irrigating the drain between the folds with a tepid aseptic fluid under weak pressure. The infectious secretions with which the drain is impregnated are thus washed out. About 10 to 20 gm. of pure or 5 per cent. carbolyzed glycerin are allowed to trickle between the folds of the tampon, or a 2 per cent. solution of hydrogen dioxid. It was applied merely as a prophylactic measure in 26 out of 62 cases drained in this way. He describes the cases in detail and also the anatomic conditions which render this method of drainage so effectual in the formation of a resistant cicatrix.

**81. Early Symptom of Pleuritis with Effusion.**—Przewalski noticed in 14 cases of pleuritis with serous effusion and in 5 with a suppurative, that the intercostal spaces were invar-

iably narrower and exhibited considerable resistance on the affected side. This symptom was most manifest in children and in the very early stages of the affection. The ribs seem to draw nearer together over the lesion, analogous to the contraction of the muscles in the course of articular lesions, mentioned in the text-books as the "fixed attitude of the members." He suggests that the reason why this "fixed attitude" of the ribs has not attracted attention hitherto, is that it is not very pronounced, and hence this reflex contracture of the internal intercostal muscles has been overlooked.

**82. Resection of the Knee.**—Sykow considers the results of surgical intervention on a tuberculous knee quite satisfactory if the limb is left in a normal position, the ends of the bones grown together and the limb not more than 3 or 4 cm. shorter than the other, with the use of it in 3 or 4 months. THE JOURNAL has mentioned the excellent results he obtained in a case of extensive defect in the lower jaw by cutting out a slab from the jaw on one side and slipping it across the breach until it rested in a recess cut out for it in the other side of the jaw. He has applied this same principle of autoplasmic restoration of the defect to the treatment of a tuberculous knee after resection of the diseased joint. He counted in this case as in the first on the regeneration of the so-called intermediate or congenital callus. Its formation is promoted by the introduction of a foreign body between the ends of the bone marrow. The patient was a young man of 18. After resection of the knee a semicircular segment of bone was sawed out of the lower third of the femur. It was inserted between the sawed ends of the femur and tibia and covered with periosteum from the femur. The patient was able to walk on the limb in three months. It is no shorter than its mate, and skiagraphy shows the two bones firmly welded together. The patient walks easily and has recovered his health.

**83. Manual Reposition of Luxations Without Narcosis.**—Roloff has been very successful in reducing dislocations of the shoulder by applying slow, gradual extension. The patient lies on the floor on his back. The arm is slowly pulled, gradually increasing the traction but never making it vigorous. At the same time the arm is gradually abducted, until it is in an almost vertical position, parallel to the axis of the body. The traction should not require much effort. By the time the abduction is complete the head is already in its socket and the arm can be slowly lowered, supporting the head in its place from the axilla. When correctly done this maneuver causes no pain, but the extension is experienced as relief by the subject. The attention of the patient is always diverted, and all manipulation of the parts and reflex contracture is avoided. The patients were all robust workmen in his experience and in the one case in which it failed, the reduction was accomplished later under chloroform. About three to thirteen minutes are required for the intervention. It is on the same principle as Stimson's extension by weights, but dispenses with all apparatus. The traction should simulate that of a weight.

**84. Differentiation of Pentosuria.**—Bial emphasizes the necessity of differentiating between pentosuria and diabetes. In all the cases of the former that have been published, the condition was mistaken for diabetes, and the patients were subjected to annoying restrictions of diet which were absolutely useless. He has modified the orcin test so that the practitioner can test the urine for pentose in a few moments with absolute precision. No boiling is required. He keeps the pentose reagent ready mixed and adds 4 or 5 c.c. to 2 or 3 c.c. of the urine to be examined. He heats the mixture until the first bubbles begin to rise, when green flakes are precipitated or the fluid merely turns green, according to the proportion of pentose. Normal or diabetic urine is not colored green by the reagent. The formula is 1 to 1.5 gm. orcin to 500 gm. fuming hydrochloric acid. About 25 to 30 drops of a 10 per cent. solution of ferric chlorid are then added, and the reagent is ready for use. It is also valuable for the determination of glykuronie acid with slight modification.

**85. Granular Degeneration of Red Corpuscles.**—Loewenthal remarks that guinea-pigs are so sensitive to external condi-

tions that the granular degeneration of the red corpuscles noted after intraperitoneal injection of tin chlorid, etc., can not be attributed exclusively to the injections. He observed granular degeneration when the animals were kept in the cellar without medication. The reds resumed their normal composition after the animals were placed in the open air, but the granulation was again apparent when they were returned to the cellar. The granular degeneration also appeared out of doors when the weather was cold and damp.

**86. Chronic Appendicitis.**—Lenzmann has had occasion to observe two more patients who had suffered for two and eight years with severe attacks of pain in the stomach, umbilicus and liver region and constipation. They had been treated for gallstone colic without effect. All the organs seemed to be sound. Palpation revealed a slightly enlarged appendix and it was possible to elicit by pressure the specific pains previously experienced. The pains and constipation were permanently banished by removal of the appendix, which was found in a condition of chronic inflammation. The nerves of the region had probably shared in the inflammation and induced the neuralgia in the stomach, etc., which characterized both cases—evidently true neuralgia of the abdominal sympathetic.

**88. Treatment of Gastric Ulcer.**—Pariser unconditionally enforces rest in bed as the primary requisite in the treatment of a gastric ulcer. He has derived great benefit from a mixture of chalk and talcum with or without magnesia which he orders in the place of the more expensive bismuth. The mixture is fully as effective as the latter in forming an aseptic crust over the ulcer. He does not use a sound, but has the patient drink 60 gm. in a glass of water on an empty stomach and then lie quietly on his back for three-quarters of an hour.

**91. Bone Marrow in Infectious Diseases.**—Fraenkel relates in detail the findings in a large number of infectious diseases in which he found the familiar germs in certain parts of the bone marrow during the corresponding disease. They were found most constantly in the red marrow of the vertebrae, less frequently in the ribs. The number of bacteria in the blood did not always parallel the number to be found in the marrow. The pyogenic staphylococci and streptococci were frequently found in the marrow even in the simplest local as well as in general affections, in peritonitis, putrid bronchitis, phlegmons, otitis media and ulcerative pulmonary tuberculosis. The bacteria which make their way into the marrow are the cause of various anatomic changes in it, such as hemorrhages, accumulations of pigment, fibrinous exudates and myelitic and necrotic foci.

**94. Cholagogue Effect of Rinsing the Stomach with Nitrate of Silver.**—Ehrlich proclaims that after rinsing the stomach according to his technic with .5 liter of a hot 1 per 1000 solution of silver nitrate, on alternate days, the liver commences to increase in size, greenish diarrhetic stools follow for a time, and in case of cholelithiasis, gallstones are liable to be voided. After a few days the diarrhea and tumefaction of the liver subside, and with them all the disturbances. This treatment is indicated in all severe cases of chronic cholangitis or cholelithiasis, especially when the latter is complicated with cholangitis or cholecystitis. The contra-indications are the same as for simple lavage of the stomach. The benefit is due partly to the mechanical and thermic effect of the filling and emptying of the stomach in the preliminary rinsing with hot water at 110 to 122 F. The solution of the nitrate is left in the stomach .5 to 2 minutes and is then evacuated. This procedure is repeated once and then the stomach is rinsed with pure hot water until the fluid is clear. The patient can eat immediately without injury. A small amount of the nitrate solution escapes into the duodenum, as evidenced by the inevitable diarrhea. As it passes the orifice of the bile duct the mucosa of the duct is irritated and the lumen narrowed. At the same time the secretion of bile is increased by reflex action, as is shown by the swelling of the liver. As the inflammation in the bile duct subsides and the lumen is clear once more, the accumulated bile escapes under high pressure and sweeps out the gallstones. Experience on patients has shown that the same effect can be

attained by administering the silver nitrate per os, but the results are not so constant as by the technic recommended, and the metallic taste in the mouth is disagreeable and takes away the appetite. He has applied the rinsing technic on 75 patients, with no unwelcome effects except slightly increased nervousness in 3. Of the 22 followed to date, 63 per cent. were cured without recurrence; 31.8 per cent. with recurrence, and 4.5 per cent. were not affected. In one case he had an opportunity to inspect the mucosa of the stomach in a patient who had been treated in this way shortly before. It was much congested, but there was no trace of scab formation. The intervention is useful to differentiate gallstones or carcinoma in the gall-bladder. In one case no trace of a tumor could be discovered, until after twelve rinsings of the stomach the liver was reduced in size to such an extent that a hard tumor in the gall-bladder could be palpated and the operation confirmed the diagnosis of carcinoma. The benefit derived from the measure in cholelithiasis and its failure in case of gastric ulcer is another instance of its value as a differentiating measure. The rinsing requires ten to fifteen minutes at a time, and as severe intoxication would follow if a large amount of the nitrate solution were left in the stomach, he always accustoms his patients to the procedure by preliminary lavage of the stomach until convinced that they will allow the rinsing to be completed. One of his patients voided 3 gallstones the size of a bean and another 33 the size of a hazelnut. Both have been completely cured.

**95. Production of Nerve Stimulants by the Organism.**—Adler suggests that the internal secretion of certain organs must act on other organs by the intermediation of the nervous system. Consequently their secretion is a nerve stimulant.

**102. Bacteriemia.**—Kretz observes that the invasion of the blood by disease germs may assume various clinical aspects. In one form the blood may become infected without an initial local effect, as in malaria, Malta fever and relapsing typhus. In another form there may be typical infection of the blood from a local point of invasion, as in anthrax and typhoid fever. The germs may be carried into the blood by the leucocytes, as in gonorrhea and probably also in lepra, or swept into the lymph current, as in infection from strepto- and diplo-cocci, or penetrate through some vascular lesion, as in tuberculosis or plague, etc. The invasion of the blood may be secondary to another infection, as in smallpox, measles or scarlet fever. The old terms sepsis and pyemia should be discarded and substituted by local infection with toxemia, metastatic inflammation, etc., reserving the term bacteriemia to express a condition for which we have no name at present.

**108. Tetanus.**—Pfeiffer reports 22 cases of tetanus and has collected 93, which he reviews. He states that the mortality of the cases treated by Behring's antitoxin is 52.7 per cent. while it is only 36.3 per cent. in 88 cases treated by Tizzoni's antitetanus serum. It seems evident, he remarks, that tetanus in Italy runs a milder course than elsewhere. Omitting the 21 cases reported by Italian physicians, the mortality is 46.2 per cent. In 14 of his personal cases in which no specific treatment was instituted, the mortality was 50 per cent.

**111. Artificial Post-Operative Lagophthalmos in Egypt.**—Osborne states that trichiasis is frequent in Egypt, and barbers and old women have a way of treating it identical with that described in the seventh century. They pinch a fold in the lid and clamp it in a slit in a piece of a reed. In the course of two weeks the skin becomes necrotic and drops off. Osborne has had a number of patients come to him in this condition, the operation having removed too large a portion of the lid, thus leaving the eye exposed. He pleads for the organization of "flying squadrons" of ophthalmologists to carry aid to the many sufferers from ocular affections throughout the country. These "flying squadrons" have been extremely successful in Germany and Russia in the campaign against trachoma. They are especially needed in Egypt to save the many sufferers from the practices of the ignorant.

**114. Surgical Aspects of Bilharzia of the Rectum.**—Madden recommends palliative operative measures to relieve the patient of the most distressing symptoms. He removes the

mass in the lower rectum, irrigates with lysol and inserts a morphin and belladonna suppository. The bowels must be kept confined for three days, after which they are assisted to act by a saline aperient or glycerin enema. This intervention must be repeated as the symptoms recur.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume V. Obstetrics, Edited by Reuben Peterson, A.B., M.D., Professor of Obstetrics and Gynecology in the University of Michigan, and Henry F. Lewis, A.B., M.D., Instructor in Obstetrics and Gynecology in Rush Medical College. April, 1902. Cloth. Pp. 226. Price, \$1.25. Chicago: Year-Book Publishers.**

**DISINFECTION AND DISINFECTANTS. A Treatise upon the Best Known Disinfectants. Their Use in the Destruction of Disease Germs, with Special Instruction for Their Application in the Commonly Recognized Infectious and Contagious Diseases. By H. M. Bracken, M.D., Professor of Materia Medica and Therapeutics, University of Minnesota. Second Edition. Cloth. Pp. 129. Price, \$1.00. Chicago: Trade Periodical Company. 1901.**

**A MANUAL OF TOXICOLOGY. A Concise Presentation of the Principal Facts Relating to Poisons, with Detailed Directions for the Treatment of Poisoning, also a Table of Doses of the Principal and Many New Remedies. By Albert H. Brundage, A.M., M.D., Ph.D., Professor of Toxicology, Physiology and Hygiene, in the Brooklyn College of Pharmacy. Cloth. Pp. 354. Price, \$2.00 net. Brooklyn: Henry Harrison Co. 1901.**

**A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition. Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume IV. Illustrated by Chromolithographs and \$59 Half-tone and Wood Engravings. Cloth. Pp. 872. Price, \$6.00. New York: Wm. Wood & Co. 1902.**

**PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. A Series of Eighty Plates, Comprising More Than One Hundred Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics. By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, N. Y. Part X. Philadelphia and London: J. B. Lippincott Co. 1901.**

**CONTRIBUTIONS TO PRACTICAL MEDICINE. By Sir James Sawyer, Knt., M.D., Lond., F.R.C.P., Lond.; F.R.S. Edin.; F.S.A.; Senior Consulting Physician to the Queen's Hospital. Third Edition. Revised and Enlarged. Cloth. Pp. 209. Price, \$0.50 (in England). Birmingham: Cornish Bros. 1902.**

**FIRST REPORT OF THE NEW YORK STATE HOSPITAL FOR THE CARE OF CRIPPLED AND DEFORMED CHILDREN, for the Ten Months Ending Sept. 30, 1901. Hospital Located at Tarrytown, N. Y., 1901. Paper. Pp. 22. Albany: J. B. Lyon. 1902.**

**HARE-LIP AND CLEFT PALATE. By R. W. Murray, F.R.C.S., Surgeon, Davis Lewis Northern Hospital, Liverpool. Cloth. Pp. 29. Price, \$0.75 (in England). London: J. & A. Churchill. 1902. Philadelphia: P. Blakiston's Son & Co.**

**REPORT OF THE VITAL STATISTICS OF THE CITIES OF HAVANA AND GUANABACO, Made by Brigadier-General Leonard Wood, U. S. A. Military Governor. February, 1902. Major W. C. Gorgas, Medical Corps, U. S. A., Chief Sanitary Officer.**

**FIFTY-THIRD ANNUAL REPORT OF THE BOARD OF TRUSTEES AND SUPERINTENDENT OF THE CENTRAL INDIANA HOSPITAL FOR INSANE, for the Fiscal Year Ending Oct. 31, 1901. Paper. Pp. 95. Indianapolis: Wm. B. Burford. 1902.**

THE PENNSYLVANIA SOCIETY FOR THE PREVENTION OF TUBERCULOSIS. Report for the Year Ending March 1, 1902. Paper.

REPORT OF ST. VINCENT'S INSTITUTION FOR THE INSANE for the Year 1901. Paper. Pp. 29.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., April 17 to 23, 1902, inclusive:

Raoul A. Amador, contract surgeon, now at Chattanooga, Tenn., is relieved from further duty in the Department of Cuba and assigned to duty with the 7th Cavalry, at Chickamauga Park, Ga.

William C. Gorgas, major and surgeon, U. S. A., previous orders revoked; on the discontinuance of the Department of Cuba he will take station at Havana, Cuba, to continue his investigations into the relationship between yellow fever and the mosquito.

John D. Hall, lieutenant-col. and deputy surgeon-general, member of a retiring board at San Francisco, Cal.

Henry F. Hoyt, major and surgeon, Vols., now at San Francisco, Cal., is relieved from duty in the Division of the Philippines and will report for temporary duty at Fort Douglas, Utah.

Jefferson R. Kean, major and surgeon, U. S. A., leave of absence for three months granted, to take effect on his return from Cuba.

Preston S. Kellogg, contract surgeon, from Fort Missoula, Mont., to accompany troops to Alaska.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a retiring board at San Francisco, Cal.

Clarence J. Manley, lieutenant, asst.-surgeon, U. S. A., leave of absence for one month granted.

John N. Merrick, contract surgeon, now at Columbus, Ohio, is relieved from further duty in the Division of the Philippines and assigned to duty at Fort Missoula, Mont.

Joseph Pettyjohn, contract surgeon, now at San Francisco, Cal., is relieved from further duty in the Division of the Philippines and will proceed to Vancouver Barracks, Wash., reporting for duty in Alaska.

Henry D. Snyder, captain and asst.-surgeon, U. S. A., member of a board at Fort Columbus, N. Y., vice Major William H. Corbusier, surgeon, U. S. A., for the examination of candidates for admission to the U. S. Military Academy, West Point, N. Y.; also, detailed to represent the Medical Department of the Army at the American Congress of Tuberculosis, to be held in New York City, May 14 to 16, 1902.

Arthur C. Stokes, contract surgeon, former orders directing him to proceed from Omaha, Neb., to San Francisco, Cal., en route to Manila, P. I., revoked.

Halsey L. Wood, contract surgeon, leave of absence for one month and fifteen days granted.

### Appointments, Promotions, Retirements, Etc..

of Army Medical Officers, recorded in the Adjutant-General's Office, between March 15 and April 15, 1902:

**Regular Army, Retirements.**—Col. Charles P. Kimball, assistant surgeon-general, April 7, 1902, for disability incident to the service, Section 1251, Revised Statutes; First Lieutenant Marshall M. Cloud, asst.-surgeon, March 25, 1902, for disability incident to the service, Section 1251, Revised Statutes.

**Volunteers, Appointments.**—To be asst.-surgeons, with the rank of captain: James E. Mead of Michigan, contract surgeon, Feb. 10, 1902; Herbert M. McConathy of Kentucky, contract surgeon, Feb. 12, 1902; James B. Pascoe of New York, contract surgeon, Feb. 19, 1902; Edward A. Southall of New York, contract surgeon, Feb. 20, 1902; Edward T. Gibson of Minnesota, contract surgeon, Feb. 28, 1902; Joseph L. Sanford of Virginia, contract surgeon, March 1, 1902.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending April 26: Asst.-Surgeon F. M. Murson, ordered to duty at the Naval Hospital, Norfolk, Va.

P. A. Surgeon D. N. Carpenter, detached from Naval Hospital, Newport, R. I., and ordered to the *Illinois*.

Asst.-Surgeon A. M. Fautleroy, detached from the *Illinois* and ordered to the Naval Hospital, Newport, R. I.

Asst.-Surgeon R. W. Plummer, detached from the *New Orleans* and ordered home to wait orders.

Pharmacist C. O'Leary, detached from the Torpedo Station, Newport, R. I., and ordered home to wait orders.

Pharmacist W. H. Huntington, detached from the *Constellation* and ordered to the Torpedo Station, Newport, R. I.

The following order was issued from Headquarters, Department of Cuba, April 14, 1902: Surgeon John W. Russ, U. S. N. (retired), will be relieved from further duty in the Sanitary Department of the City of Havana, May 20, 1902, and will accompany the Department Commander to Washington.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the United States Marine-Hospital Service for the seven days ended April 24, 1902:

P. A. Surgeon W. G. Stimpson, to proceed to Mendocino and Napa, Cal., for special temporary duty.

Asst.-Surgeon S. B. Grubbs, relieved from duty in the Hygienic Laboratory and directed to report to Surgeon J. H. White for special temporary duty; then to proceed to Gulf Quarantine Station, relieving Asst.-Surgeon J. T. Burkhalter. Granted leave of absence for 10 days from April 23.

Asst.-Surgeon W. C. Hobdy, to proceed to Brunswick Quarantine and assume temporary command of the service during the absence, on leave, of Acting Asst.-Surgeon R. E. L. Burford.

Asst.-Surgeon J. Goldberger, upon being relieved at Reedy Island Quarantine, to proceed to Tampico, Mexico, for duty in the office of C. S. Consul.

Asst.-Surgeon C. W. Vogel, granted leave of absence for 15 days from May 12.

Asst.-Surgeon C. E. D. Lord, detailed to represent the service at the annual session of the State Medical Association of Texas, at Dallas, May 6-9.

Asst.-Surgeon J. T. Burkhalter, upon being relieved by Asst.-Surgeon S. B. Grubbs, to report to him for duty and assignment to quarters.

Asst.-Surgeon J. S. Boggess, relieved from duty at Philadelphia and directed to proceed to Reedy Island Quarantine Station and report to medical officer in command for duty and assignment to quarters, relieving Asst.-Surgeon J. Goldberger.

Acting Asst.-Surgeon F. M. Clarke, granted leave of absence for 20 days from April 14.

Acting Asst.-Surgeon J. T. McCormac, Department letter of March 15, granting 15 days' leave of absence, amended so that said leave shall be for 6 days from March 30.

Acting Asst.-Surgeon-W. T. Walker, granted leave of absence for 18 days from May 1.

Junior Pharmacist Carl Stier, to proceed to Memphis, Tenn., and report to medical officer in command for temporary duty and assignment to quarters.

### APPOINTMENT.

Carl Stier, of Alabama, appointed junior pharmacist April 23, 1902.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended April 26, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, April 5-12, 4 cases; San Francisco, April 6-13, 15 cases.

Colorado: Denver, April 5-12, 9 cases.

District of Columbia: Washington, April 12-19, 1 case.

Florida: Jacksonville, April 12-19, 9 cases.

Illinois: Belleville, April 12-19, 1 case; Chicago, April 12-19, 14 cases; Galesburg, April 12-19, 1 case.

Indiana: Evansville, April 12-19, 2 cases; Indianapolis, April 12-19, 22 cases, 1 death.

Kansas: Wichita, April 12-19, 2 cases.

Kentucky: Covington, April 13-20, 10 cases.

Louisiana: Shreveport, April 12-19, 7 cases.

Maine: Portland, April 12-19, 1 death.

Massachusetts: Boston, April 12-19, 9 cases, 4 deaths; Chelsea, April 12-19, 1 case; Malden, April 12-19, 2 cases; Somerville, April 12-19, 1 death.

Michigan: Detroit, April 12-19, 10 cases; Grand Rapids, March 29-April 19, 4 cases; Ludington, April 12-19, 5 cases.

Nebraska: Omaha, April 12-19, 33 cases.

New Jersey: Camden, April 12-19, 1 case; Newark, April 12-19, 29 cases, 4 deaths.

New York: New York, April 12-19, 56 cases, 8 deaths.

Ohio: Cincinnati, April 11-18, 17 cases; Cleveland, April 12-19, 2 cases; Dayton, April 12-19, 1 case; Toledo, April 12-19, 2 cases.

Pennsylvania: Altoona, April 12-19, 4 cases; Columbia, April 14-21, 6 cases; Erie, April 12-19, 8 cases; Johnstown, April 12-19, 2 cases; Philadelphia, April 12-19, 26 cases, 1 death; Pittsburg, April 12-19, 5 cases.

Rhode Island: Providence, April 12-19, 2 deaths.

South Carolina: Greenville, April 5-12, 2 cases.

South Dakota: Sioux Falls, April 12-19, 1 case.

Tennessee: Memphis, April 12-19, 13 cases; Nashville, April 12-19, 1 case.

Vermont: Burlington, April 5-12, 1 case.

Washington: Tacoma, April 6-13, 5 deaths.

West Virginia: Wheeling, April 5-12, 1 case.

Wisconsin: Green Bay, April 13-20, 10 cases; Janesville, April 6-13, 2 cases; Milwaukee, April 12-19, 3 cases.

#### SMALLPOX—FOREIGN.

Austria: Prague, March 29-April 5, 5 cases, 1 death.

Belgium: Antwerp, March 29-April 5, 9 cases, 3 deaths.

Canada: Winnipeg, April 5-12, 6 cases.

China: Hongkong, March 1-8, 4 cases, 2 deaths.

Colombia: Cartagena, March 29-April 6, 1 death.

France: Marseilles, March 1-31, 2 deaths; Paris, March 29-April 5, 3 deaths.

Great Britain: Birmingham, April 5-12, 1 case; Dundee, March 29-April 5, 4 cases; Glasgow, April 4-11, 18 cases, 2 deaths; Leeds, March 29-April 5, 2 deaths; Liverpool, March 29-April 12, 7 cases; London, March 29-April 5, 376 cases, 54 deaths; Plymouth, April 5-12, 1 case.

India: Bombay, March 18-25, 8 deaths; Calcutta, March 15-22, 11 deaths; Karachi, March 16-23, 13 cases, 4 deaths.

Italy: Naples, March 22-April 5, 20 cases; Palermo, March 29-April 5, 6 cases, 2 deaths.

Mexico: Mexico, March 31-April 6, 1 case, 1 death; Vera Cruz, March 29-April 12, 4 cases, 3 deaths.

Russia: Moscow, March 22-29, 21 cases, 3 deaths; Odessa, March 29-April 5, 5 cases, 1 death; St. Petersburg, March 29-April 5, 8 cases, 2 deaths.

Turkey: Smyrna, March 2-30, 1 death.

#### YELLOW FEVER.

Dutch Guiana: Paramaribo, to March 1, 31 cases, 21 deaths.

French Guiana: Cayenne, to March 27, 1 case, 1 death; Mana, to March 27, 1 case, 1 death; St. Laurent, to March 27, 32 cases, 21 deaths.

Mexico: Vera Cruz, March 29-April 12, 6 cases, 5 deaths.

#### PLAGUE.

India: Bombay, March 18-25, 751 deaths; Calcutta, March 15-22, 420 deaths; Karachi, March 16-22, 90 cases, 79 deaths.

#### CHOLERA.

China: Hongkong, March 1-8, 1 case, 1 death.

India: Bombay, March 18-25, 9 deaths; Calcutta, March 15-22, 86 deaths.

Straits Settlements: Singapore, March 1-8, 2 deaths.

### THE EVOLUTIONARY ASPECT OF INFECTIOUS DISEASES, WITH ESPECIAL REFERENCE TO THE LOCAL VENEREAL DISEASES.\*

G. FRANK LYDSTON, M.D.

Professor of the Surgical Diseases of the Genito-Urinary Organs,  
Medical Department, State University of Illinois; Professor  
of Surgery, Chicago Clinical School; Surgeon  
to St. Mary's Hospital,  
CHICAGO.

The evidence of evolution in general and of infectious micro-organisms in particular, has been so overwhelming during the last decade that it is surprising that teachers of science who renounce the doctrine of evolution can still be found. A few weeks since, however, I heard a distinguished teacher of physiology say that the theory of evolution was untenable and unscientific, and that Darwin was not a scientist. This despite the facts that manifold and indubitable proofs of organic evolution exist, and that evolutionary law controls and binds together all the natural sciences and is the very cornerstone of sociology, and indeed, all else of human interest. But the experimental and laboratory craze is upon us and we are worshipping the new gods instead of weighing their potentialities and assigning to each its proper place in scientific medicine. Experimental facts are valuable in so far as they lead to a more rational philosophy and method in medicine. In the abstract they are well-nigh valueless. It is not to be denied that the great man in medicine to-day is often he who discovers a lot of things which, as Josh Billings says, "aint so." A single intelligent working theory is worth a bushel of useless or misapplied "facts." Facts, both experimental and clinical, have often been stumbling blocks in the way of progress. Facts which are fruitful in philosophy are the guiding stars of science. Barren facts are unprofitable and available chiefly as curiosities.

The view of infection which I assumed twenty years ago and have since published from time to time, had as its basis the belief that infectious diseases may arise spontaneously—a view old-fashioned enough to command respect. Inasmuch as the specific germ entity had then come to the fore and the theory of spontaneous generation had long since been apparently overthrown, the generation of infectious diseases *de novo* seemed impossible—and it was so ordered by my critics.

To my mind there was but one way out of the difficulty—the application of an evolutionary law, so familiar and simple that it is a matter of surprise that it should be necessary to mention it in connection with germ diseases. This law is, that all living organisms must adapt themselves to their environment. With such adaptation necessarily comes differentiation of type and species. *Pari passu* with such differentiation a modification of properties develops. Such modification of properties may be favorable or unfavorable to the germ; favorable or unfavorable to the animal or vegetable organism which it infests. The law and its effects thus bears not alone upon the germ, but also upon the victim upon which it feeds. There are not separate laws for parasite and host—one great omnipotent law governs the organic history of both. The life history of the germ is but an epitome of all things organic. The alternative of this view of disease is obvious—primordial specific creation.

It was with some difficulty that I was able to make some of my critics understand that I was not upholding the theory of spontaneous generation of germs, but the spontaneous generation of new and virulent properties in hitherto innocuous germs, and a natural variation of type and pathogenic effect of germs supposed to be invariably specific.

The laboratory investigator has been witnessing the operations of the law of germ adaptation year by year, but the profession has just begun to grasp it, and the average laboratory worker has been unable to "see the woods for the trees." Did the earlier, and for that matter do some of the latter-day laboratory workers believe that man can add to or subtract from the phenomena of nature? They have been very much in the position of the fly on the chariot wheel in the ancient fable, who exclaimed: "See what a dust we raise." Anything which can be accomplished in the laboratory must needs depend upon the operations of a law many times more potent in the life history of the germ in its normal habitat than in the laboratory.

The theory of the spontaneous development of infection has been combated, through ignorance of evolutionary law, on the ground that the theory of spontaneous generation was long ago upset—which had nothing to do with the case. Now I do not wish to be understood as supporting that apparently exploded theory, nor is expatiation upon it essential to the treatment of my subject, but I nevertheless wish to make a few remarks upon it as showing that even it is a question which is not susceptible to dogmatism. Harvey's law, "*Omne vivum ex ovo*," or its modification, "*Omne vivum ex vivo*," established by the labors of Spallanzani, Schulze, Schwann, Schröder, Dusch, Hoffmann, Chevreul, Bonnet, Cohn, Tyndall, and most conclusively by

\* Lecture delivered by invitation before the Buffalo Academy of Medicine, Jan. 21, 1902, and Creighton Medical College, Omaha, Neb., March 5, 1902.

1. Evolution of the Local Venereal Diseases, Western Med. Reporter, vol. II, 1889, and vol. XII, 1890. Lecture before the St. Louis Academy of Medicine, 1889. Paper read before the Chicago Academy of Medicine, 1892.

Pasteur, is generally believed to have closed the question of spontaneous generation. Tyndall, e. g., showed that living organisms in decomposing fluids are explained either by pre-existence of similar forms in the fluid, or access of air containing them. Pasteur's experiments later confirmed Tyndall's position. But, what have we to say of Huxley, who, with true scientific agnosticism, says in effect, "We know nothing of the beginnings of life, and are not justified in assuming premises which demand for their support and rational formulation a foreknowledge of such beginnings." It is hardly scientific for us to assert that, inasmuch as we have no positive evidences of spontaneous generation either in the past or at the present day, it does not occur and never could have occurred in the history of the world. As Huxley says, "we know nothing of the beginnings of life." Time was when the stellar system was limited. With telescopes of increased power came a broadening out and amplification of the maps of the heavens. Perchance microscopy is as crude to-day as was telescoping in its earlier years. Improvements in optical apparatus and teachings may one day open up to study biologic worlds yet unconquered, analogous to the recent observations of the formation of stars and suns from nebulae; a substantiation of La Place's views which at least places them upon a higher plane than mere theory.

Accepting the nebular hypothesis of the origin of the solar system it is evident that life first appeared upon our earth under conditions differing widely from those now existing, differing more especially as respects atmospheric oxygen, light and heat. It is noteworthy that some species of bacteria are at present capable of existing in the absence of free oxygen, without light and at a temperature relatively high. No other organism can duplicate this life history, and this fact alone should shed some light upon the beginnings of life. Taking into consideration the fact that the primal terrestrial conditions must have been peculiar as compared with those now existing, who shall say that the inorganic might not have become organic. We certainly are not justified in formulating biologic laws to fit aforesaid, or, rather, we are presumptuous in putting limits upon primal evolutionary possibilities, especially in view of the inexorable law that the rapidity and degree of differentiation of living organisms are inversely to their complexity of organization. The higher the type the less the organism is swayed by evolutionary law, and vice versa.

I will assume, then, that the evolutionary history of certain germs may have begun far back in the history of the earth, at a period so remote that we can not even guess at their environmental conditions. Such germs might well be as insensitive to existing influences as is the host upon which they prey. It is by no means impossible that the environmental conditions necessary to the spontaneous generation of living entities exist and are operating about us even now. That definite germ types as we observe them are interchangeable along evolutionary lines is susceptible of proof. The fact that typically specific micro-organisms are not immediately interchangeable is no evidence against the operations of evolutionary law, any more than is the unchangeableness of highly differentiated organic types. As already remarked, the rapidity and extent of progression along evolutionary lines is inversely to the degree of differentiation already attained.

Evolution in its relation to disease is of necessity a double-purposed law. It controls and modifies the host and must have at least an equal influence upon the para-

site. If the law already formulated be correct, evolution influences some parasites even more profoundly than it does the host. The influence of evolution upon disease so far as the host is concerned has long been recognized. The history of measles is an illustration. You are all familiar with the history of this disease among the Sandwich Islanders. A disease which, with the whites, is usually a trivial affair, proved extremely fatal among the Kanakas. Among the whites, evolutionary adaptation and heredity have had full sway. The Kanakas, however, were not so protected. Smallpox is a very fatal disease among the negroes as compared with the whites. Both measles and smallpox among the whites, however, are occasionally very severe. I venture the suggestion that such cases are atavistic. I have elsewhere<sup>2</sup> expressed the opinion that the progressive decrease in the virulency of syphilis is susceptible of an evolutionary explanation. The human race has become fairly well syphilized by this time, and hereditary immunity should count for something in a disease which in its active period so seldom kills as to permit the race to secure the full benefit of hereditary immunity, if such there be. Precocious, or malignant, syphilis I believe to be evidence of atavism of micro-organisms combined with atavism of susceptibility.

The influence of evolution on the host has been so long understood among progressive medical thinkers that it is remarkable that its influence upon the parasite should have attracted so little attention. Hereditary immunity is met with in vegetable life. The cotton plant is subject to a parasitic disease known as wilt. Certain plants are not susceptible to it, others attacked by it, survive. The primary immunity of the former and the acquired immunity of the latter are transmitted to their descendants. Advantage has been taken of this and, ere long, wilt will no longer menace the cotton planter.

Disease is incident to the life of every animal. Disease is largely dependent upon living micro-organisms. As we study the evolution of the animal so should we study the evolution of the disease germs that affect it. Every phase of organic evolution is subject to adverse as well as favorable elements of various kinds. Each organism is relentlessly pursued by foes of a higher or lower order of evolutionary development and differentiation. Even the germs of disease themselves are, in some cases, pursued by other germs which destroy them. How much of this phase of organic evolution is manifest in infectious diseases of a mixed type science has not yet determined. We know that some germs prepare a favorable field for other germs. The converse seems also to be true. The paucity of the bacillus *icteroides* and the presence of innumerable colon bacilli and pus cocci in many fatal cases of yellow fever may mean more than we at present realize, and are no argument against the accuracy of Sanarelli's views. It is unfortunate that the human system should be the battle ground of the warring micro-organic factions. Man, with his superior power born of the forbidden fruit—knowledge—has been able to contend pretty successfully against most of the elements unfavorable to him. He has not acquitted himself so brilliantly as regards those apparently insignificant little foes, the germs of disease. Evolutionary law he may not abrogate, though he may sometimes direct and modify its operation.

As man himself has become differentiated through environmental influences, so have his foes become differ-

entiated. As a consequence of adaptation upon both sides, man has become more susceptible to the attacks of some disease germs and more resistant to others. It may well be that certain varieties have become extinct, whilst others have sprung up by virtue of vicious evolution of primarily innocuous germs, becoming so modified as to bear no resemblance to the parent stock. By careful research along these lines we may eventually find that many diseases, at this epoch markedly dissimilar, may have become so through germ differentiation. Perchance also we may discover and control the circumstances upon which such differentiation depends. Herein may be the seed from which the medical science of the future will spring.

As bearing upon the question of the upspringing of hitherto unrecognized infectious diseases the history of epidemic cerebrospinal meningitis is very interesting. Practically, if not entirely, unknown until within the last hundred years, its character and ravages have come to be only too well recognized. The recognition of an identical epidemic disease in horses is of especial interest as suggestive of evolutionary possibilities.

Early in 1884, in the course of a correspondence with Dr. De Gorrequer Griffith of London, my attention was called by him to what he termed "The Unity of Poisons in Disease." He subsequently sent me his pamphlet on the subject and was good enough to associate with me in an article published several months later.<sup>3</sup> As showing his position I will quote briefly:

"In the year 1875, I first observed that what is termed scarlatina in the puerperium is frequently not really scarlatina. I believe that there are two forms of scarlatina: the orthodox, viz., that contracted from a person infected by scarlatina, and the septicemic, or toxemic, viz., that evolved or generated *de novo*, by autogenetic blood-poisoning, such as occurs in puerperal cases, or as a consequence of heterogenetic blood-poisoning, such as arises (where no scarlatina had existed before) from drains, sewers, imbibition or ingestion of deleterious articles of food; and from decomposing animal or vegetable substances.

"While carrying on this investigation, I was struck with the unity of origin in certain cases of puerperal fever and typhoid. Pursuing the inquiry I found that from the same source would spring erysipelas, scarlatina, typhoid and puerperal fever, diphtheria, sore umbilicus in infants, sore eyes, sore mouth and sore throats, embracing a very wide area of inflammation and inflammatory conditions of palate, tonsils and pharynx; passing still further on in the respiratory tract, the larynx, the bronchi, the pleura and even the lung would be involved: so that toxemic or septicemic laryngitis, bronchitis, pleurisy, pneumonia, and pleuropneumonia, attacking a variety of persons, all, as in the cases of the other forenamed ailments, viz., toxemic, typhoid, etc., as I call them to distinguish them from the orthodox, may be traced to the same causes. The same is true of hepatitis, diarrhea, dysentery, cholera, enteritis, and a large number of affections hitherto considered to be utterly distinct and independent diseases. Hence I formulated the view of unity (as regards origin) of poison in the diseases enumerated and in many others usually considered to be separate and entirely distinct.

"Intercurrent symptoms occurring in the course of an affection such as scarlatina—symptoms ordinarily termed complications—may become primary motors of disease, originating a fresh epidemic; it may be fresh

inasmuch as it would differ from that in the course of which it was itself evolved. For example, diphtheria not unfrequently is met as a complication of scarlatina (I would say it was part and parcel of the scarlatina), which, in this instance, would be spoken of as the primary disease, the other as being secondary. The diphtheria might be conveyed to a number of persons, even to such a number as to constitute a fast-spreading epidemic. Then this diphtheria would cease to propagate itself, or would cause something quite different to be evolved in the person exposed, or in the course of these evolutions it would revert to that which set it going, viz., scarlatina. There often originate or evolve in a number of the exposed, certain other symptoms, usually considered sequelæ, but not actually part of the scarlatina. Here an outburst of something apparently altogether different from scarlatina and diphtheria takes place. This sometimes causes another new evolution: or again, reverts to scarlatina or diphtheria or both combined. Were it to leap forward it would cause to be evolved, in a certain number of cases, a very ulterior sequela of scarlatina—say rheumatism or rheumatic fever, and heart or pericardiac affections. Nephritis (the scarlatinal form) may be evolved without any other intermediate symptoms being noticed.

"By unity of poison I mean, not that the poison is always the same, but that the one poison—whatever it may be—often originates several so-called different affections, apparently so widely different as to be considered in every respect specific."

In the joint article mentioned I took the liberty of suggesting that the mass of clinical facts as collected by Dr. Griffith was incoherent and had no tangible bond of continuity. I suggested, moreover, that his theory had an untenable, entirely chemical basis which served to make confusion worse confounded. I then expressed the view that if he had taken the living disease germ as his starting-point, following it through its evolutionary phases and taking into consideration the varying susceptibility of the host, some tangible view of the correlation of the infectious diseases might have been developed. Both Dr. Griffith and myself were ignorant of the now well-recognized possibilities of mixed infection, whilst he apparently adjoined the germ altogether. Our joint article, however, was the foundation of the more mature conception of germ evolution which I published shortly afterwards, and which has served as the basis of the present lecture.

The frequent difficulty of differentiating etiologically processes which clinically seem unequivocally specific has long been familiar to the profession. Note, for example, the varying phases of septic infection, phlegmon, erysipelas, septicemia, puerperal fever, pyemia—who can tell always where the etiologic line of demarcation begins or ends? The apparent identity of origin of these processes, the type forms of which are so dissimilar clinically, is a matter of common experience, despite varying bacteriologic observations. The precise relative weight of the putrefactive toxi-proteid and micro-organic elements in such conditions is very difficult of determination. The microscope has done us yeoman service, but has it explained all? Is there not a great beyond which has thus far defied our present optical resources? Is not the truth to be found rather in the direction of bio-chemical research and observation along evolutionary lines rather than in the study of specific microscopic forms alone?

A beautiful illustration of the confusion that exists as to the germ etiology of supposedly different diseases

is hemorrhagic septicemia. Hueppe groups under this heading a number of diseases once supposed to be separate pathologic entities, such as the rabbit septicemia of Koch,<sup>4</sup> the wildseuche and rinderseuche of Bollinger and others, and the schweineseuche of Löffler. It is just beginning to dawn upon some of these observers that they have perhaps been studying and classifying the varying evolutionary phases of the same disease germ.

The views expressed in this present paper necessarily conflict with the dominant school of germ pathology, of which Koch is the acknowledged leader. The theory of specific constancy of germs owes its popularity to the atavistic tendency of the human mind to revert to the primitive conceptions of savages and children, who explain phenomena by the dominance of a living entity. The savage with his gods and demons and the child with his Santa Claus and fairy tales are on a psychic parity. Such explanations are simple and once advanced are fondly clung to. When renounced it is with all the pain incidental to the renunciation of an easy-going pet idea. It may savor of boldness, not to say presumption, yet I am constrained to say that Pasteur, and following him, Koch and his school, while they have done much for the material accuracy of medicine, have nevertheless played an active part in deranging the substratum of rational philosophy upon which rests the entire superstructure of medical science.

The results obtained in our laboratory modification of infectious germs depend largely upon degenerative changes in the micro-organism, the species growing not only less virulent but more feeble. In certain instances, however, the micro-organisms lose their pathogenicity while remaining as vigorous or more vigorous than ever. The loss of pathogenic properties and a transformation into mere saprophytes have been observed. Careful observation has shown that the properties of pigment formation, development of toxins and fermentive power in micro-organisms are dependent upon the quality of adaptation. The micro-organism is versatile because swayed by evolutionary law. Koch's doctrine of the immutability of specificity in pathogenic micro-organisms is no longer tenable. Accepted ten years ago, his dictum has not borne the cross-fire of laboratory observation. Personally, I have never believed in the primal specific creation of micro-organisms any more than of any organism, and of necessity have always been skeptical as to their immutability.

The theory of specific constancy of infectious micro-organisms at first gave rise to the most optimistic views of therapeutic possibilities. Having discovered the germ, the sole remaining requirement was to find a remedy which would kill it and thus cure the disease. The lay mind is even now dominated by this fallacious belief. As time went on, however, the profession began to appreciate the insuperable obstacles often found in the way of specific therapeutics. This I will formulate as the law that the resistance of organisms, like their rapidity of multiplication and development, is inversely to their degree of differentiation. The operations of this law are at once obvious. The cells of the host, more complexly organized and more highly differentiated than the parasitic microbe, yield to destructive influences which are resisted by the latter. Herein was our first defeat. Not until the life history of the microbes of disease began to be better understood was there any marked improve-

ment in therapy as an outcome of our knowledge of the specific properties of germs. And then came serum-therapy, the rationale of which is explicable along strictly evolutionary lines. Even our views of local antiseptics have been so modified that the supplying of conditions unfavorable to germ development, rather than an attempt to destroy the germ, dominates modern surgery—evolutionary principles again.

The believer in the specific creation of micro-organisms or even in the present existence of unvarying micro-organic entities has, of course, demanded the missing link. He, like his anti-Darwinian prototype, can not be convinced without it. It must be remembered, however, that the visible complete physical transformation of even a single species is not necessary to prove the evolutionary progression and differentiation of microbes, nor is it consistent with evolutionary law in general. Unicellular organisms probably hew as closely to the line as do the more highly differentiated and more complex organisms, in which the cell is not the whole but merely the unit, albeit the basic element. The germ shows progression along evolutionary lines within its own biologic range, and adheres to its own physical type—so far as our present methods enable us to determine—whatever the variation in its properties may be. Its properties of specific pathogenesis, culture, color reactions and varying degrees of virulency, may be the result, on the one hand of atavism, and on the other of environmental adaptation, but it is always a variation of type, not of species. The fact that microbes of certain specific diseases are unvarying in kind in their pathogenic properties does not controvert the evolutionary view of infectious diseases. *Per contra*, it is evidence of the strongest kind that microbes are subservient to evolutionary law. The type in such cases has become so fixed that, while a variation in degree of pathogenesis may occur, there can be no variation in kind. Far back in their life history, however, a number of specific germs may have had a common root stock. Just here the co-relation of vaccinia and variola is strongly suggestive. Along the same lines does not the possibility of a remote relationship between *la dourine*—so-called animal syphilis—and *lues* suggest itself? To be sure there is a wider difference between the human and animal syphilis than exists between vaccinia and variola, but experimental inoculation and serum-therapy with human syphilis and *maladie du coit* might lessen this difference. Besides, the period of time past covered by the evolution of syphilis and *la dourine* may be immensely greater than the period of existence of variola and vaccinia. Then, too, we should not expect precisely similar evolutionary results of disease germs in dissimilar animal species. Apropos of the possible animal origin of human syphilis it might be well to recall the fact that Martineau, nearly a quarter of a century ago, claimed to have syphilized a monkey. The case was presented to the Parisian Academy of Medicine and appeared to be quite clearly defined. It was, however, rejected by the Academy as a demonstration of animal susceptibility to syphilis. The extraordinary susceptibility to the *Simiadae* to tuberculosis is suggestive along these lines. I will also again refer you to the co-relation of human and equine cerebrospinal meningitis.

So far as the influence of evolutionary law is concerned, it is of little importance whether micro-organisms in general, and pathogenic germs in particular, belong to the animal or to the vegetable kingdom. The operations of the law are the same. The practical importance of the question lies in the fact that if micro-

4. Hueppe: Principles of Bacteriology.

organisms are neither animal nor vegetable, but of a lower, more indeterminate type than either; they are still more susceptible than either to evolutionary law, for the rapidity and degree of evolutionary variation is inversely to the degree of differentiation already attained.

If the evolutionary relation of the most primitive animal and vegetable organisms be proven, the primal root stock must of necessity be of a lower, indeterminate type. Those whose fame rests upon classification may protest if they will; this is the law. Overthrow or controvert it, and the warp and woof of evolutionary doctrine falls to the ground, for the theory can show no beginning. The beginning or primary impulse must operate along evolutionary lines, else we must needs either assume a position of complete scientific agnosticism or accept the mosaic cosmogony as a basis for biology. The view of the intermediary position of bacteria between animals and plants was held and taught by me to my classes twenty years ago. It is gratifying to me to note the confirmation of that somewhat immature view by so eminent a teacher as Hueppe,<sup>5</sup> who says, "Bacteria are able to construct their body substance out of various kinds of nutrient materials, and also to produce organic pigments, fermentation products or poison characteristic of individual species, and are able to do this analytically or synthetically with almost equal ease. This ambidextrous metabolic power exists among bacteria as among no other living things. These organisms consequently occupy morphologically, and, still more, physiologically, a place intermediate between animals and plants."

I am still more pleased with Hueppe's summing up of the question of specificity: "Koch's belief that the constancy of specific disease-producing bacteria renounces at the outset a scientific explanation. With the abandonment of Koch's position—which has been made inevitable by the discoveries of the last ten years—bacteriology has progressed beyond the natural history stage and become scientific." The interchangeability of the properties of distinctly vegetable non-pathogenic micro-organisms and those of a distinctly pathogenic type is worthy of consideration along evolutionary lines. The vegetable molds, which are not ordinarily capable of producing infection, but produce superficial surface diseases, may become saprophytic and produce internal infection. A case was recorded by Wagner where the *oidium albicans* of thrush entered the circulation via a wounded vein, and produced fatal cerebral mycosis. Several varieties of *mucor* and *aspergillus*—usually non-pathogenic organisms—have been shown to be transformable into saprophytic infectious parasites by adaptation.

Laboratory proofs of bacterial evolution are not wanting. The life conditions of micro-organisms have been experimentally changed. Obligatory anaërobic parasites have been adapted to aerial life and obligatory aërobes to an anaërobic environment. Hueppe has cultivated as an aërobe the *spirillum rubrum*, which normally produces its red pigment in the absence of oxygen. He has also compelled the comma bacillus—a strict aërobe—to adopt anaërobiosis, and has altered the life conditions of the actinomycosis fungus. Kitt has cultivated aërobically the obligatory anaërobic bacillus of symptomatic anthrax. Both Hueppe and Scholl have shown that the comma bacillus develops more toxicity in the absence of air than in its presence and that the poisons produced

by anaërobic saprophytic micro-organisms are destroyed by oxidation. Hueppe produced typical choleraic diarrhea in animals, with artificially bred anaërobic comma bacilli. Cholera germs that have become anaërobic by culture lose their virulency rapidly when exposed to the air. Cultures of the pneumonia coccus take the same course. Cholera germs have been found to change spontaneously. When young they are virulent. Exposure to the air and advancing age render them impotent. Although aërobic they do not have time or the proper medium to enable them to become adapted to ordinary atmospheric conditions. The adaptation of pathogenic germs to environment is shown in pure cultures of certain anaërobic types upon gelatin and agar. They become accustomed to metabolism of oxidation, and the pathogenic products are oxidized as fast as formed. Virulency is thus lost.

(To be continued.)

## A PRELIMINARY REPORT ON THE TRANSMISSION OF PATHOGENIC GERMS BY THE COMMON HOUSE-FLY.

JACOLYN MANNING, M.D.

EAU CLAIRE, WIS.

William Hamilton Gibson, the naturalist and artist, called attention to a troublesome parasite of the housefly, the microscopic, red, false scorpion. A careful scrutiny of a sheet of adhesive fly-paper in use will show many victims of this inconvenient little handicap, which, once anchored to the fly's leg, remains there, an animated and persistent tag.

A more serious and fatal enemy is the fly fungus, which "silences more house-flies than all the traps and poisons devoted to their extermination." This germ-scourge of flies kills them swiftly, and continues to grow with such rapidity that it perforates the body of its host and spreads around him on the wall or window-glass a white shroud of mold, from which spores are wafted, to the peril of next year's flies. That the housefly acts as host to this fungus is apparent to any one who will examine with a hand lens one of the suspended and inanimate forms seen often during the fall months.

The habit of affording house room, whether willingly or unwillingly, to all comers, brought *Musca domestica* prominently before the profession in the last decade, when he fell under suspicion as a carrier of infection in acute intestinal diseases.

The investigation of the Army Medical Commission during the Spanish-American war practically established the fact that the fly is an important factor in the dissemination of typhoid fever.

Victor Vaughan, a member of that commission, stated that flies undoubtedly served as carriers of typhoid infection, giving as reasons for his belief: "They swarmed over fecal matter in the latrines. They visited and fed on food prepared for the soldiers in the mess tents. In some instances, when lime had been recently sprinkled over the contents of latrines, flies, with their feet whitened with lime, were seen walking over the food. Officers, whose mess tents were protected by means of screens, suffered less proportionately from typhoid fever than those whose tents were not so protected. Typhoid fever gradually disappeared in the fall of 1898, with the approach of cold weather and the consequent disabling of the fly."

This possibility had been foreseen, for Surgeon-General Dr. Sternberg issued a circular in April, 1898,

5. Hueppe: Op. cit.

giving careful directions concerning hygiene, stating: "No doubt typhoid fever, camp diarrhea and probably yellow fever are frequently communicated to soldiers in camps through the agency of flies, which swarm about fecal matter, . . . and directly convey infectious material attached to their feet, or contained in their excreta, to the food which is exposed while being prepared at the common kitchen, or while being served in the mess tent."

An Italian scientist, Celli, demonstrated in 1888 that flies fed on the pure cultures of bacillus typhi abdominalis were able to transmit virulent bacilli into their excrement; and the agency of flies in the transmission of the spirillum of Asiatic cholera has been observed by many scientists.

Dr. L. O. Howard, of the U. S. Board of Agriculture, recently published the results of experimental work with the house-fly and other diptera extending over a period of five years. He considered that from a scientific and practical viewpoint there was needed a careful investigation of the insect fauna of human excrement, and especially of the flies that breed in human excrement, or are attracted to it. Of the 71 species of diptera that were found breeding in, or frequenting human excrement, the common house-fly (*Musca domestica*) is reported "abundant;" as also its near relatives, the little house-fly (*Homalo-myia canicularis*) "moderately abundant," and the stable-fly (*Muscina stabulans*). To ascertain the practical bearing of this fact, numerous collections were made of the diptera frequenting kitchens and pantries. "In all, 23,087 flies were examined which had been caught in rooms in which food supplies were ordinarily exposed, and which may safely be said to have been attracted by the presence of these food supplies." Of this number 98.8 per cent. were the common house-fly, while the little house-fly and the stable-fly composed one-half of the remainder.

Dr. Howard gives an opinion: "That *Musca domestica*, . . . in such cities and towns, or in such portions of cities, as are well cared for and inhabited by a cleanly and respectable population, may not be considered an imminent source of danger; it is . . . under other conditions, a factor of the greatest importance in the spread of intestinal diseases."

Of the biting fly (*Stomoxys calcitrans*) Dr. Howard states: "They resemble the house-fly very closely. The fact that they enter houses before storms gives rise to the common expression, 'Flies begin to bite before a rain.' From their biting and blood-sucking habits, this insect has been suspected, in common with the true horse-flies, of carrying the bacillus of anthrax, or malignant pustule, and there is no reason why it should not transfer any blood-inhabiting micro-organism from domestic animals to man, or from one man to another."

Of another very minute fly (*Hippelates flavipes*) Dr. Howard says: "The flies are very abundant, especially in the South, where they are found swarming about the eyes of animals and human beings. They are said by Hubbard to be responsible for the transmission of the disease known as 'pinkeye,' occasionally prevalent, especially among school children in Florida. The . . . species is perhaps often responsible for the carriage of putrefactive germs to open wounds, and is indirectly the cause of blood poisoning."

From the foregoing statements may we not expect to find the ever-present house-fly a direct factor in the transmission of the micro-organisms of wound infection?

It has been said that the mosquito carries with her the most perfectly constructed of inoculators, and the house-fly has, in the specialized structure of each terminal tarsus, a well-adapted brush for the transmission of adhering germs. The pads, or so-called suction discs, on each foot, are rayed with minute hairs, which again terminate in more minute discs; and Chambers states that the last named "exude a liquid substance which probably serves to make adhesion more perfect." In experimenting it was found that every footprint of an infected fly on sterile culture media was followed by a discreet colony of the germ; 30 to 40 distinct colonies sometimes appearing after one journey of the fly across the surface of the culture media.

In the experiments that follow common house-flies were used. They were caught in the kitchen of a dwelling-house, in a physician's office, and in one instance in a lying-in chamber. They were confined separately under reversed tumblers placed on note paper. A watch glass containing a small portion of the infected material was thrust under the tumbler, and when curiosity had taken the fly across the material, he was seized with a sterile forceps wrapped with cotton, and liberated just at the mouth of a tube of sterile blood serum. One stroll across the culture media and the tube was inverted over the flame of an alcohol lamp, which incinerated the fly and sterilized mouth of tube. The cotton plug and rubber cap of the tube being adjusted, it was placed in an incubator at 37° C. for twelve hours.

The tubes of sterile culture media were obtained prepared for use, from a well-known laboratory.

On September 7 the dressings from an infected hand were obtained, the dressings were soaked with blood serum, there were several areas of greenish and bright green pus, and an offensive odor diffused on opening them. The surgeon stated the wound had shown an obstinate phlegmonous extension, with localized edema. A portion of the dressing was placed under an inverted tumbler and two flies confined with it. They immediately lighted on the dressing, crossing it repeatedly before preparations were completed for removing them. In a few moments they moved slowly and appeared quite stupid.

Fly A was assisted into a tube of sterile blood serum with sterile forceps.

Fly B walked into a second tube through a perforation in the note paper over a tumbler.

In each case, after the fly crossed the surface of medium, the tube was inverted over an alcohol flame, destroying the fly; the mouth of tube and cotton plug were flame sterilized, the plug and rubber cap adjusted, and the tubes placed in incubator. After eighteen hours these tubes were removed from the incubator and presented practically the same appearance; the surface of medium was freely dotted with small brown colonies, the upper surface of medium presented a pale-greenish tint. Three days later inspection showed the colonies entirely coalesced, the upper one-half of media in each tube was a deep bluish-green, the lower one-half a dull orange; liquefaction of the media had begun at lower end of slant. Cover spreads made from these cultures and stained with Loeffler's alkaline methylene blue showed a pure culture of a small bacillus with rounded ends.

In following out the necessary cultures on different media for diagnosis, in every instance the pure culture, as transmitted by the original flies, was obtained.

A slant culture on glycerin agar-agar and one on nutrient agar-agar, made on September 9, developed

typical colonies in twenty-four hours and showed the fluorescent stain of the media, which later developed to a deep bluish-black.

A stab culture in blue litmus gelatin gave an acid reaction in forty-eight hours, the lower portion of the medium turning pink, while at the same time the upper portion became the pleasing translucent green.

A stab culture in nutrient gelatin, in four days, showed liquefaction in funnel form, with fluorescence of upper portion of medium.

All of the cultures, when opened, emitted an offensive and purulent odor. From all of these characteristics the germs were identified as the bacilli of green pus. The bacillus of green pus, Gessard's micrococcus pyocyaneus, or the bacillus des grün-blauen Eiters, is a widely distributed germ, found in purulent and serous wounds, and in the viscera of human cadavers. It is an aërobic, facultative anaërobic, liquefactive, motile, chromogenic and pathogenic germ; in its chromogenic function two pigments are formed, one fluorescent green, the other blue pyocyanin.

The satisfaction felt on coming into possession of a germ, so easily identified and tenacious of existence, has increased each week, as other experiments much less satisfactory were undertaken.

September 25 two flies were segregated with pus from a case of salpingitis; a cover-slip spread of the pus showed many streptococci and a few large, fat bacilli. Each fly was induced to walk across a tube of blood serum, and then one of nutrient agar-agar, and the tubes were incubated twelve hours. An interruption of ten days followed, during which time the tubes were left in cold storage. On examination, October 7, one blood serum and one agar tube were fuzzy with many colored molds; the second tube of nutrient agar showed nine colonies of a viscid, discrete, whitish growth. The blood serum tube showed many larger colonies, and three communities of the orange sarcinae.

From the colonies on agar, cultures were made on all the various diagnostic media.

A stab culture in glucose gelatin presented large slanting bubbles of gas along the line of growth in three days. There was no liquefaction of media in any of the gelatin cultures.

A stab culture in blue litmus gelatin gradually turned the blue color of the media to a clear claret red. Cover-slip preparations made and stained showed an almost pure culture of a fat bacillus, which, from its appearance and manner of growth, was identified as the colon bacillus.

Welch states that "one of the leading rôles of this germ is to invade territory already occupied by other bacteria, or previously damaged;" and by its vigorous growth it had almost exterminated the streptococci that were numerous in the infective material.

On October 7 three flies were confined with a watch-glass containing a small amount of typhoid stool, from a typhoid whose temperature had just dropped to normal. Each fly was introduced separately into sterile tubes of blood serum, and promptly dispatched after crossing media. At the end of seventy-two hours two of the tubes presented many small round, moist, grayish colonies, while the third one was fuzzy with gray mold. A cover-glass spread from cultures showed many small bacilli with rounded ends, and a few faintly staining cocci. In a hanging drop preparation from the blood serum culture, the bacilli were seen to be actively motile, spinning and shooting about in a surprising manner. When grown in blue litmus gelatin there was no change

in the color of the media; and in glucose gelatin there was no production of gas. There was no liquefaction of media in the various cultures in gelatin. The clump leaction was not tried, but the growth responded to all the other tests for identification of the bacillus typhi abdominalis.

On September 20 ten tubes of sterile blood serum were used. In each tube a common house-fly which had no known acquaintance with infectious material, was introduced and left in tube one minute, or until it had crossed surface of medium. After twelve hours in the incubator five of the tubes showed many minute colonies while five showed no growth. At the end of seventy-two hours eight of the tubes showed diffuse and varied growths, while two of the tubes were apparently sterile. Of the eight infected tubes three presented a noticeable appearance. No. 10 (1) showed over 100 colonies dotting the blood serum at irregular distances, the colonies were minute, discreet, raised, moist, color of medium. No. 10 (2) presented thirty-three colonies, irregular in outline, crenated edges, depressed centers, a light brownish yellow. In No. 10 (3) the surface of medium was covered with a moist, irregular, creamy-appearing growth.

I regret to say that these experiments were not carried on to the determination of the germs present. They will be repeated with an investigation of the pathogenic qualities of the bacteria present, at an early opportunity.

On November 2 a fly was confined with some sputum from a case of bronchitis in its fourth week. A cover-glass spread of the sputum showed diplococci, tetrads, and many staphylococci and streptococci. Two tubes of blood serum were infected by the fly, and after forty-eight hours' incubation showed manifold and surprising growths. Prominent among the colonies were several of a golden-yellow color and glistening surface. From these colonies cultures were made on the various diagnostic media. A streak culture on Loeffler's blood serum made a rapid growth, the growth elevated with wavy edges, and a shining golden surface. A streak culture on Koch's blood serum developed less color and sunk into the medium, channeling a bed for itself, otherwise the medium did not liquefy. On nutrient agar the growth was rapid, of a creamy-white color, with yellow at margin of growth. A gelatin stab culture showed a cloudy liquefaction following stab. Stained cover-glass spreads of the blood serum cultures showed masses of small cocci, which were identified as the staphylococci pyogenes aureus.

Two tubes inoculated with flies taken from a lying-in chamber early in September, showed after incubation, one sterile tube and one tube containing many colonies of orange and white sarcinae; these germs are non-pathogenic and appeared sooner or later in a majority of the cultures produced by fly infection.

On one of the tubes—fly infected from the case of salpingitis, a single colony of bacillus prodigiosus appeared. This germ grows with the production of a brilliant orange-red pigment and is the origin of the miracle of the supposed bleeding wafers. It is non-pathogenic, but its chemical products are toxic and form a part of the Coley sarcoma mixture.

Molds grew so rapidly on many of the fly-infected tubes that only a few are presentable for inspection, suggesting the probability that flies are often fungus-ridden whether transmitting pathogenic germs or not.

The molds appeared more rapidly and certainly the last month than the first, and also during the past four weeks the flies have walked less briskly across the surface of media, but dragging across; the colonies were not discreetly rounded.

During the experimentation 44 culture tubes have been subjected to fly infection; of this number 41 tubes showed colonization at the end of 48 hours, 3 tubes remaining apparently sterile.

The following germs have been transmitted by fly infection, isolated and pure cultures obtained: Pathogenic germs—*bacillus pyocyaneus*, *staphylococci pyogenes aureus*, *bacillus typhi abdominalis*, *bacillus coli communis*. Non-pathogenic—*bacillus prodigiosus*, *sarcinae aurantia*, *sarcinae alba*, molds and fungi.

## THE FIXATION OF A MOVABLE LIVER AND REPORT OF A CASE OF HEPATOPEXY.

J. H. CARSTENS, M.D.

DETROIT, MICH.

On account of the great rarity of floating or movable livers, I have looked over the literature and have had others help me at it. I find that only about 98 cases have been reported, from which we are able to draw some conclusion in the etiology, symptoms and management of this class of cases. As far as I have been able to find the record of cases is as follows:

A. Catini<sup>1</sup> reports a case with severe nervous symptoms, in a patient aged 54. The organ could be replaced.

R. Piatelli<sup>2</sup> reports a case of a woman aged 56. A bandage could not be worn.

E. A. Meissner<sup>3</sup> gives a case of a married woman of 39, a displaced liver apparently following pregnancy. She was much improved by wearing bandage.

G. Barbotta<sup>4</sup> states a case of a woman aged 37, also caused by parturition.

F. Vogelsang<sup>5</sup> reports a case in a very quarrelsome woman, middle-aged, of a floating, movable liver, which was caused by tight lacing.

F. N. Winkler<sup>6</sup> reports a case of a woman of 29. There was general ptosis, following the lifting of a heavy burden, and stabbing pain in the right side. It could be moved to the left side.

P. Muller<sup>7</sup> states a case of a woman aged 57, with a movable liver complicated with an ovarian tumor. It was verified by autopsy.

Salomone-Marino<sup>8</sup> gives a case of a woman aged 50, who had pain only on turning on left side. He also reports a second case in a woman aged 48, of movable liver, the result of a fall.

G. Leopold<sup>9</sup> states a case in a woman aged 54, who was poorly nourished. It never could be replaced.

C. Vicoli<sup>10</sup> gives a case of a woman aged 70, with the cause given as excessive lacing.

W. Sutugin<sup>11</sup> reports a case of a married woman at the age of 41, which was much relieved by wearing bandage.

G. Tempini<sup>12</sup> states a case of a woman aged 72, accompanied by heart lesion; the kidney could be replaced and kept there by hands.

N. P. Wassiljew<sup>13</sup> gives a case, aged 39, where the spleen was very movable and a movable kidney on the right side. He also reports a second case, a coachman aged 31, who was taken with a violent pain on the right side after great exertion. A third case of a carpenter, aged 47, seemed to be caused by severe cough.

L. Concato<sup>14</sup> tells of a case, woman, aged 60, who had pain. She was a very tight lacer and was relieved by

bandage. She finally died, but there was no autopsy made.

F. Chovstek<sup>15</sup> gives a case of a married woman of 53, mother of 12 children. Labors were always very difficult. She was ordered to wear bandage.

L. W. Blet<sup>16</sup> reports two cases without giving age or histories. Both died from heart lesion.

F. Koehler<sup>17</sup> states a case. Married woman of 54 had falling of the womb, which was relieved by a pessary. Liver could be replaced and held with the hand. She had no pain.

W. Pepper<sup>18</sup> states a case in a married woman, 41, occurring after childbirth; it was accompanied by flatulency.

J. W. Legg<sup>19</sup> reports a case of a man aged 36, with decision apparently due to coughing. It was verified by autopsy.

F. Chovstek<sup>20</sup> reports a case in a woman aged 68, accompanied by dropsy and swelling of the lower extremities.

C. Hochhalt<sup>21</sup> gives a case of a man who had raised a heavy sack, then sank down senseless. Elastic bandage and pad were given as relief.

H. Rodsewitch<sup>22</sup> reports a case of a woman of 18. Tight lacing during pregnancy caused movable liver.

F. Chovstek<sup>23</sup> gives a case in a man of 45, who was a great beer-drinker and led a sedentary life. After gymnastic exercise he found floating liver. He had little trouble from it.

J. W. Runeberg<sup>24</sup> reports a case. In session of May 7, 1881, Runeberg showed a woman with floating liver and also spoke of another case reported by him. Pippingskold spoke of a case of liver dislocated observed by him many years since in a woman of 50 years, which was brought on after severe puerperal peritonitis; she died afterwards of carcinoma of the uterus and the dislocation was confirmed at the postmortem.

F. Schott<sup>25</sup> gives a case of a married woman of 40. Jaundice existed for five or six years; during this time she had repeated attacks of vomiting, diarrhea, constipation, general weakness and was greatly emaciated. She had catarrh of the stomach, bronchitis, etc. A floating liver was found and a bandage with a pad was ordered. After ten months patient was much improved and stronger.

J. Trush<sup>26</sup> reports a case of a widow aged 68. Movable liver followed a severe fall. It was verified by autopsy.

Nicola de Dominicis<sup>27</sup> reports that he observed some years ago a woman who had a wandering liver, in whom, having married and then become pregnant, the liver was returned to the normal place by the pregnancy and was not again displaced.

F. Schwartz<sup>28</sup> gives a case of a man aged 38, with fever and chills occasioned by jaundice. He returned to the hospital a number of times.

Julius Kranols<sup>29</sup> reports a case in a married woman of 38, accompanied with dropsy. Postmortem showed cancerous liver.

J. Penna, diagnosed by J. B. Arini,<sup>30</sup> reports a young girl. Her clothes were too small around the body. Floating liver was diagnosed and confirmed by Arini. It was relieved by special corset.

J. Maack<sup>31</sup> gives a case of a single woman of 35. Had a tumor in the right side in the ileo-cecal region, which was found to be a liver and could not be relieved by bandage.

G. Kispert<sup>32</sup> states a case in a married woman of 43, who had severe labors followed by fever. Afterwards

tumor was found; in fact, two, with an hourglass contraction.

S. Salome-Marino<sup>33</sup> reports a case. Single woman, with middle body causing trouble when she walked; was attacked with peritonitis in 1873, which caused fixation of the liver in the right ileo-cecal region. He reports a second case in a washerwoman of 49, who died of hemiplegia. Another woman, aged 33, had severe tympanites. Another woman, aged 44, died of sarcoma of the jaw; an autopsy was held. Another case was that of a man aged 55. There was a history only of intermittent fever with tympanites. He also reports a case of a married woman aged 34. There was poor digestion brought on after her sixth confinement. Another case of a woman aged 21, a silk-worker, was caused by lifting a heavy weight. He reports the case of a woman aged 27, apparently followed after dancing until she was exhausted five or six evenings in succession.

A. Perrone<sup>34</sup> gives a case of a married woman aged 58, who fell downstairs. Kidney was very movable.

H. Rosenkranz<sup>35</sup> states a case of a married woman aged 48, who was seized with severe vomiting, and pain in the abdomen. This was followed by ascites in the edema of the legs. This disappeared after two months. Dislocated liver was found, which could be turned without trouble on its sagittal axis.

R. Pichevin<sup>36</sup> states a case of a movable lobe of the liver and a floating kidney.

K. Szigethy<sup>37</sup> gives a case of a man of 42, with difficulty of breathing, jaundice and ascites caused by wandering liver.

E. H. Parker<sup>38</sup> reports a case of a child, 10 months old, with a tumor, which he thought was a movable liver, but was pronounced sarcoma of the kidney by others.

E. Maragliano<sup>39</sup> reports the case of a woman 51 years old, with movable liver, evidently accompanied or caused by cancer.

George Curtius<sup>40</sup> gives a case of a married woman aged 41, with very movable liver, which was relieved by wearing a flannel bandage.

M. Einhorn<sup>41</sup> states the case of a carpenter aged 57, who had always been healthy; it came on suddenly, with severe chill and dizziness, accompanied by vomiting and pain.

Gonterman<sup>42</sup> reports a case of a girl nearly a year old, taken with whooping cough complicated with peritonitis. She was later taken with diarrhea and meteorism and became greatly emaciated. After this a tumor was noticed. Sudden death occurred, which was supposed to be due to twisting of the pedicle, although no post-mortem was made.

S. Salome-Marino<sup>43</sup> gives a case of a wandering liver which suddenly appeared in a girl of 5 years without producing severe symptoms.

J. F. Binnie<sup>44</sup> reports a case of a single woman aged 47, a music teacher. She had a tumor on the right side three years, and an attack of jaundice six months before; an exploratory laparotomy was made. On opening the abdomen, a floating liver, rotated and freely movable, was found. On its surface were nodules like hepatic carcinoma.

Schtscherbakow and Rudow<sup>45</sup> give a case of a woman aged 35; after eleven births it occurred, apparently, by getting up too soon after severe confinement. She wore a bandage.

G. N. Kreider<sup>46</sup> reports a case of a veteran of the War of the Rebellion; it was thought that the liver was

loosened by lifting heavy casks. The patient declared that he suffered no inconvenience from the organ.

Richelot<sup>47</sup> reports a case of painful movable tumor in the right iliac fossa, which proved to be the displaced liver. He operated and three months later the relief was still complete.

Dr. V. Poli<sup>48</sup> reports a case of movable liver in a woman aged 29. He operated with success.

M. Albert Mathien<sup>49</sup> reports a floating liver in a woman aged 53; he operated: the patient recovered.

J. Buchholz<sup>50</sup> records a case of floating liver in a widow aged 50; abdominal bandage was applied, with complete recovery.

Dr. S. Weissenberg<sup>51</sup> of Jelissawetgrad, reports a case of *hepar migrans s. mobile*, as follows: F. H., female, aged 43; abdominal bandage gave temporary relief. Operation refused; patient died later.

Prof. W. Leube<sup>52</sup> of Wurzburg, Germany, reports a case of floating liver as follows: S. H., peasant's son, aged 17; operation; recovery.

Dr. Benjamin Hellier, M.R.C.S.,<sup>53</sup> reports a case of enlarged gall-bladder, with inguiform appendix of the liver, in a married woman aged 32. Exploratory incision was made. Patient made excellent and rapid recovery.

Bastianelli<sup>54</sup> operated in a case of floating liver in a woman aged 37. A diagnosis of cancer and displacement of kidney had been made. Good recovery occurred.

Lannelongue and Faguet<sup>55</sup> of Bordeaux, operated in a case of floating liver, diagnosed as tumor of the large intestine, with good recovery.

Dr. J. E. Graham, London, reports three cases of movable liver. Case 1. Female, aged 62. Abdominal bandage was used; patient made rapid recovery. Case 2. J. R., aged 32; patient died from other causes; post-mortem revealed floating liver. Case 3. M. T., boy, aged 17, with transposed and movable liver. Treatment was not stated.<sup>56</sup>

Bobroff reports a movable liver in a woman aged 50 years; laparotomy was performed; there was marked improvement.<sup>57</sup>

Glubinsky<sup>58</sup> reports a case of movable liver in a female aged 38; operation, with complete recovery.

Dr. Frederick A. Packard reports a case of floating liver in a male laborer aged 40. Exploratory puncture was made, with recovery.<sup>59</sup>

Pean records a case of movable liver in a female aged 29 years; operation, with complete recovery.<sup>60</sup>

Dr. Felix Franke reports two interesting cases of floating liver as follows: Case 1. A. Sch., woman, aged 23; operation and subsequent good recovery. Case 2. H. W., widow, 41 years old; laparotomy, with good recovery.<sup>61</sup>

Areilza<sup>62</sup> reports a floating liver in a male aged 20 years; laparotomy, followed by recovery.

Delagenière<sup>63</sup> records a case of floating liver in a female aged 30 years; operation and complete recovery followed.

J. Lucas Championnière reports floating liver in a female aged 35; median laparotomy and recovery.<sup>64</sup>

R. Crawford reports a case of "anteverted, wandering liver," in a woman aged 65; postmortem revealed above condition.<sup>65</sup>

Blanc reports an interesting case of movable liver in a woman aged 35; vertical incision was made, with perfect success and rapid recovery.<sup>66</sup>

P. Ferrari reports a singular case of floating liver in a girl 24 years old; operation and recovery.<sup>67</sup>

Dr. H. McNaughton-Jones reports a case of complete laparotomy in a female aged 38. There was splendid recovery.<sup>68</sup>

Dr. Aristide Muratori reports a case of movable liver, the result of probably carcinoma; in a male laborer aged 61. Operation was made, with recovery.<sup>69</sup>

Professor Einhorn, of New York, reports five cases of movable liver, as follows: Case 1. Sarah D., aged 37; abdominal bandage was employed, with rapid improvement. Case 2, aged 50; abdominal bandage and rapid improvement. Case 3, female, aged 55, with abdominal bandage, improved immediately. Case 4. David L., aged 41; abdominal bandage ordered, with marked improvement. Case 5. A. S., 25 years; full diet and bandage were ordered; marked improvement resulted.

Einhorn reports four other cases of movable liver, diagnosed incorrectly; three were pronounced cancer of stomach; the fourth as appendicitis or gallstone. Bandage relieved all symptoms. Among five other cases, wrongly pronounced gallstone colic, was that of a man aged 60. Adjustment of bandage resulted in great relief.<sup>70</sup>

Dr. N. O. Nisbet, of Charlotte, N. C., reports movable liver in a woman aged 45. Abdominal bandage relieved all symptoms.<sup>71</sup>

These cases enable us to see with reasonable certainty that the cause of a movable liver is always an injury, severe fall, heavy lifting, or, in a few cases, the development of a malignant growth in the liver.
